

Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

- + *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
- + *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
- + *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
- + *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página <http://books.google.com>

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

Alphabetical Index of Contents.

An asterisk (*) denotes Illustrations.

A Running Table of Contents will be found on the last page of each number.

EDITORIALS.	Page.	Surface Contact Railway, The Evolution of the.....	Page.	*Detroit Mun. Elec. Lt. Plant, 1898 Report.....	Page.
Alternating Currents to Elec. Traction, The Application of.....	338	Telephone Disturbances from Elec. Generators.....	410	*Enclosed Arcs, Miniature G. E.....	327
Arc Lights, Prices for City.....	486	Telegraph Lines in Cuba.....	463	*Enclosed Arcs, Ill. in Boston and Providence Department Stores by.....	408
Armatures, Spare.....	290	Tesla, Mr. and the Czar.....	486	*Enclosed Arc Ltg., A few Interesting Pointers Concerning.....	25
Automobiles, The Age of.....	87	Tesla, Mr. to his Friends.....	514	*English Ltg. and Pr. Sta. Practice, Features of.....	606
Bears and Horses.....	643	Tesla, Mr., His Friends to.....	514	*Fire Damp on Inc. Lamps.....	561
Bell Telephones in Use.....	11	Tornadoes and the Niagara Line.....	339	*French Chamber of Deputies, A Gas Engine Elec. Ltg. Plant for the.....	559
Belts, Electric.....	131	Traction in a Storm.....	587	*Glasgow, Scotland, Mun. Ltg. Plant, Port Dundas.....	51
Brakes, Agitation over St. Car.....	538	Power Trans., The Limitations of.....	202	*Goughnour Dynamos and Motors, The.....	344
Brooklyn Bridge, Trolleys on the.....	155	Treadmill Generators.....	587	*Hull Alter. Arc Lt. Regulator, The.....	63
Calcium Carbide Industry in Europe, The Present Status of the.....	155	Trolley Times, Signs of the.....	34	Jandus Arc Lamp.....	630
Car Motor Regulation, The Counter E. M. F. Method of.....	83	Trolley and Fan as Health Givers, The.....	235	*Lamp Holder, Magnetic Inc.....	637
Central Power Plants, Exhaust Steam from.....	339	Uncle Sam Needs More Room.....	411	*Lieb Park Lamp Post, The.....	387
Chicago, Elec. Ltg. Consolidation in.....	314	Volunteer Engr. Corps, Presentation to the.....	87	*Long Beach & San Pedro Elec. Co.....	388
City Light, Legitimate Ways of Getting Cheaper.....	434	Volunteer Engrs., Return of the.....	539	*Long-Schattner Prepayment Meter, The.....	561
Chicago, An Elevated Example from.....	387	War Inventions.....	235	Lynn Inc. Lamp.....	637
College Graduates? What Becomes of Our.....	314	Warning, A Timely.....	487	Madeleine, Paris, In the.....	289
Collisions at Sea, Avoiding.....	106	Warships, Elec. Power on.....	539	*Marine Enclosed Arc Lamp, G. E.....	603
Conduit Trolley, The Success of the.....	388	Westinghouse-Walker Consolidation, The.....	291	*Mechanical Plant of a Modern Commercial Building, The.....	560, 589, 611, 637
Consolidations and Cheaper Current.....	587	Wind Pr. as a Source of Elec. Energy.....	339	*Meter Tests, Notes on Some Central Station.....	3
Copper Refining, Current Density as a Factor in.....	87	Wireless Telegraphy, Practical.....	291	Miller Moths, Lights Put out by.....	330
Current, The Waste of.....	315	Women Car Conductors.....	11, 107	*"Monarch" Enclosed Arc Lamp, The.....	69
Dentistry, The Present Status of Electro.....	86			Montreal, Ltg. Consolidation in.....	571
Detroit Mun. Convention.....	130			*Multiphase System for Cent. Sta. Service, Consideration of the.....	281
Detroit Mun. Elec. Ltg. Plant, The.....	151			Ohio Elec. Lt. Assn.....	186
Dublin Jarvey, The Trolley and the.....	463			*Omaha Exposition, Illumination of the Grand Court.....	42
Elec. Ry. Outlook, The.....	234			*Pitman Grove Camp Meeting, Elec. Ltg. at the.....	201
Elec. vs. Cable Traction.....	642			Pittsburg, Allegheny County Lt. Co.....	108
Electro-Metallurgy, Progress in.....	35			Pittsburg, Knight Templar Illuminations at.....	409
Electricity as the Feeder of the Race.....	290			*"Pittsburg" Type K. Transformer, The.....	415
Electrolysis in Ry. Work, Features of.....	435			Plants, Econ. in operation of Small Light Edison Co.....	357
Electrolytic Operations, Recent Progress in.....	131			*Rushmore Marine Generating Set and Projector.....	21
Enclosed Arc, Popularity of the.....	463			*Rushmore 3-Wire Dynamo.....	465
Enclosed Arc Lamp, The.....	563			*Shelby Elec. Co., Inc. Lamps as Manufactured by the.....	358
England, Mun. Telephony in.....	106			Shooting the Chute in a Pr. House.....	433
England, Municipal Conservatism in.....	642			*Short Circuit, One Way of Finding a.....	541
Engr. Troops, Lack of.....	643			*State Capitol, Wiring the N. Y.....	355

JULY 7, 1898.

No. 531.

The Reno Inclined Elevator in a Department Store.

Fig. 4.—Landing of Reno Inclined Elevator.

ANYONE who has seen and wondered at the restless activity and untiring energy of modern shoppers will welcome any means whereby their task or perhaps his own will be made lighter and the number of miles to be walked be lessened. Not alone would a one-story department store find favor or horseless carriages on the floor be in constant demand, but elevators for which the wearisome shopper would not have to wait five minutes or more might receive hearty approval. Recognizing these facts and to lessen as much as possible the fatigue of their customers, the well-known department store of Bloomingdale Bros., occupying the entire block between Fifty-ninth and Six-

near the main entrance of the colossal establishment, and leads from the first to the second floor of the main building. Since it has been put in place over 50,000 persons have taken advantage of this novel device, and not a single accident has occurred, and, so far as we can see, there is not the remotest chance of the

FIG. 2.—FRAMEWORK OF RENO INCLINED ELEVATOR, SHOWING LOCATION OF MOTOR.

youngest or weakest person being injured or even alarmed in stepping on it for the first time. During the ride on this incline the sensations of the passengers are apparently more agreeable than when shut up in the closed cage of an ordinary elevator.

The elevator, shown loaded with a number of passengers in Fig. 1, is built against the wall of the building, where space could well be spared and where, as can be seen, it does not rob the

FIG. 1.—SIDE VIEW OF RENO INCLINED ELEVATOR, FULLY LOADED.

tieth streets, on Third avenue, New York, has been enriched lately by the installation of one of the greatest conveniences yet devised for the comfortable handling of large masses of people circulating indoors. It consists of the Reno inclined elevator, described and illustrated below, which will be remembered by our readers as having been in use for some time on the Brooklyn Bridge and at Coney Island, 200,000 people having been transported by it at these two places without a single mishap. We may here state that since the elevated trains have begun to run over the Brooklyn Bridge the Elevated Railway Company are seriously considering the installation of a Reno elevator at the New York terminal of the bridge.

The Reno inclined elevator, which may be said to fill the void between a common stairway and a vertical elevator, is installed

floor of valuable sale room. It is $3\frac{1}{2}$ feet in width, being intended for single-file service, and is built at an angle of about 25 degrees, as shown in Fig. 2. Referring to this figure, it will be seen that the structure consists of steel framework, bolted at the top to the steel floor beam or header, and similarly supported at the bottom. Near the middle it is supported by a steel column, the weight at that point being about 2,100 pounds. The moving incline consists of an endless chain, marked a in Fig. 3, rotated by a sprocket wheel b, to which are attached a number of hardwood slats, c, which are plainly shown in Fig. 5. These slats have fastened to them a series of rubber-covered ridges, d, each being about $\frac{3}{4}$ inch wide and 1 inch high. These serve as a comfortable footing for the passengers and also insure a perfectly smooth, safe landing at the upper end of the machine.

This is accomplished in the following manner, shown in Fig. 4. The feet of the passenger, which rest upon these rubber-covered ridges, are slid off as they arrive upon a comb-shaped landing, consisting of cast-iron prongs, which fit into the grooves separating the ridges d. The landing is a most agreeable and natural one, and forms a very essential portion of the machine. So perfect, in fact, is the action that even cotton waste will not catch at this point.

To each end of the wooden slats is attached a small anti-friction wheel e, made of hemasite. These roll upon the angle iron f and are also shown in Fig. 4. As will be seen, these wheels roll upon the angle irons on both their upward and downward passages and insure easy running, free from shocks and jars.

The endless chain a, besides passing over the sprocket wheel b at the upper end of the machine also passes over an idler sprocket wheel at the lower end, as shown in Fig. 2. Attached to the shaft of the upper wheel is a cut gear g, into which meshes

FIG. 5.—FRONT VIEW OF RENO INCLINED ELEVATOR, SHOWING CONSTRUCTION OF MOVING INCLINE AND HANDRAIL.

a rawhide pinion h attached to a countershaft. This shaft carries at its other end a similar cut gear i, into which meshes another rawhide pinion j, which is attached to the motor shaft. There are thus obtained two reductions in speed, each set of gears reducing the speed one-sixth, or a total reduction of one thirty-sixth. The speed of the motor, 450 r. p. m., is thus reduced to about 12 r. p. m. at the chain, which gives the moving incline a speed of 75 feet per minute.

The motor used to drive the mechanism is of the C & C iron-clad type, shown in Fig. 6. It is a 15 h. p. machine, but its winding has been changed so as to make it a 10 h. p. machine at 450 r. p. m. on a 110-volt circuit. As will be shown later, the maximum load on the elevator only requires a motor of one-half that capacity. The motor is bolted to the floor beams at the upper end of the elevator, as shown in Fig. 2, and is controlled by an automatic starting box, housed in near the lower end. To the switch of this starting box is attached a cord which leads to the upper and lower ends of the elevator, and by means of which the motor may be started, stopped or reversed.

Another essential feature of the elevator is the moving hand-rail, which is shown in perspective in Fig. 5 and in section in Fig. 3. Referring to this figure, the railing is supported on stanchions, k, placed every 3 feet apart, of a shape and fastened

in the manner shown. To the tops of these standards is bolted the steel bar l, which has cut into its upper surface a

FIG. 3.—VERTICAL SECTION OF RENO INCLINED ELEVATOR, SHOWING DETAILS OF CONSTRUCTION.

slot m. In these slots slides the bottom of a specially constructed steel chain, which is rotated by means of a sprocket wheel marked n, at the upper end of the machine. This wheel is attached directly to the main driving shaft of the elevator, so that the rail travels at the same speed as the platform, and the

FIG. 6.—C & C OPEN TYPE MOTOR, USED FOR RENO INCLINED ELEVATOR.

two appear stationary with respect to each other. There are also two idler sprocket wheels, one at each end, which are enclosed in casings, as shown in Figs. 2 and 5. The chain, which if once

lubricated remains so by its own motion, is covered over by a moulded rubber covering, to which it is securely fastened, and serves as the support for the hand of the passenger. Due to the noiseless running of the machinery, it was found necessary in order to advise people of the fact that the handrail was in motion to mould into the rubber large round white discs, which are plainly visible in Fig. 5.

As has been stated above, the moving platform travels at the rate of 75 feet per minute, or, if run continuously for ten hours, it will cover about nine miles in one day. The elevator, when fully loaded, i. e., counting one passenger for every two feet, will carry thirty-seven in one minute, or 2,200 in one hour. To find the power and from this the cost of transporting this large number of people, a very exhaustive series of tests were undertaken last week, with the following results:

Volts.	Amps.	H. P.	Remarks.
110	8.2	1.2	Elevator free.
110	16.0	2.36	5 people on elevator.
110	19.0	2.8	9 people, 5' apart.
110	20.0	2.95	11 people, 4' apart.
110	35.0	5.15	21 people, 2' apart.

Reckoning the power to cost three cents per h. p. h., it would cost seven cents to carry 1,000 passengers in one hour, which appears to be by far the cheapest means of transportation available at present.

Besides its low cost of operation, the following advantages are claimed for the elevator.

1. It makes the second floor of store buildings almost as accessible to the public as the ground floor.
2. It takes up little valuable space, and, as shown in the above installation, may be located adjacent to the wall.
3. It fulfills the fire department regulations as to a stairway, and thus does away with the stairs needed in addition to an ordinary elevator.
4. It requires no attendant to run it.
5. It is noiseless.
6. It may be started or stopped at either end by simply pressing a button.
7. It is always ready for use.
8. It will handle boxes and trunks.
9. It consumes power only in proportion to the number of passengers elevated.
10. It is absolutely safe.

Mr. J. W. Reno, the inventor of the elevator, is a mining engineer, having graduated from Lehigh University in 1883. He then went West to engage in mining work and remained there for seven years, when he came East and went into the mining department of the Thomson-Houston Company, working together with Captain Griffin and Mr. Van Depoele. He had charge of the building of several trolley roads in the South. He then took up the subject of inclined elevators, which he has brought to the stage of perfection, evidenced by the installation described above. He has also worked out during the past few years an underground railway system which appears to admirably suit the conditions found in this city.

Notes on Some Central Station Meter Tests.

BY WILLIAM D. ENNIS, M. E.

THE writer recently had occasion to test for a small lighting and power station near New York its entire electric meter system. Current was sold by the company in question both by meter and by contract. The sales had originally been on the contract basis only, but in 1891 a small investment in T.-H. meters was made, with results that seemed to justify an exclusive meter basis. From that time until 1897, electric meters of various makes, principally the old T.-H. and its successor, the General Electric meter, were gradually installed.

The complaints concerning bills were rather more numerous than is customary. A large number of these were traced to other causes, such as leaky transformers, old lamps, etc., but when

these were excluded, there seemed still to be an unusually large percentage of complaints, the cause for which was assigned to the meters.

Such rough tests as had been made had shown almost invariably that the meters were slow rather than fast. It was finally decided to make a series of tests, changing all meters that it was practicable to remove, and ascertaining the error of every meter in service. To do this was not altogether practicable, as cases were found where for various reasons it was impossible to remove the meter for a test, and all tests made with the meter in service were excluded. What was done was to collect all available meters in the station. The tests were made at the lines. Thus the meters for these most important consumers were the ones concerning which data was obtained.

The accompanying figure shows the plan of the lamp bank and instruments. It was found convenient. By means of four switches shown, the energy on either side of the meter could be read on the wattmeter, and the power required to run the meter obtained. The rheostat R was used, when necessary to adjust the voltage. The lamps were so arranged that one, five, ten, twenty-five or fifty could be thrown in or out of circuit by the switches. Any intermediate number could be connected by unscrewing a few lamps from their sockets.

FIG. 1.

onds or oftener, while the revolutions of the dial were being counted. The meter was always allowed to run for a short time before any readings were taken, and the number of revolutions counted was usually five times the number of lamps in circuit. After testing from minimum to maximum load, the test at minimum load was repeated, and if any marked difference was noted between the two tests, the entire series of tests on that particular meter was repeated.

Each meter was subjected to at least two tests. One was made (where possible) with the meter in the exact condition in which it was brought into the station. After several experimental adjustments, a final test was made, to obtain the degree of accuracy of the corrected meter. In many cases, tests were made intermediate between these two. Interesting results were obtained from tests made before adjusting, but after cleaning. The number of such tests was not sufficient to give any very reliable data, however.

Upon examining the meters as brought into the station, many evidences of misuse and neglect were noted. Seals had been broken, unmistakable evidences of tampering were found in one case, reducing the speed 50 per cent. from the normal. Meters were found which failed to start on full load; when started, some ran steadily, even on minimum loads, others stopped short, and some ran in an irregular way, the rate being at no time, however, fast; except in four examples, where the meter ran on no load.

Jewel screws were discovered tightly jammed, brushes too dirty to give proper contact, cobwebs spun around the arma-

tures and fields; and these various cases were by no means rare. Several burn-outs were noted, due to overloading. The power required to run the meters (as determined by measuring the power for a single load on each side of the meter) was excessive, averaging in eleven tests made 18.3 watts. The condition of the entire system was from both a mechanical and a commercial standpoint, thoroughly bad. This was largely due to

FIG. 2.

the fact that the meters had not been properly cared for, or protected from dishonest and clever consumers.

The voltage during the tests was kept at 54 or 108, which was the average supply voltage. Any variation from the rated voltage of the meter tended to make it slow, though for small variations this was not of great consequence. In one case, a 100-volt meter was found connected to a 50-volt house circuit, with the result that the consumer was getting a mechanical discount of about 30 per cent. on his bills.

Average, by curve	.919	Average, by curve	1.020
Average, calculated*	.900	Average, calculated*	1.014

*As explained above.

The meters tested ranged in capacity from 5 to 300 amperes, and were rated at from 50 to 110 volts. Each meter was tested as closely as possible at its rated voltage, this being obtained in some cases by connecting pairs of lamps in series, and by the

FIG. 3.

rheostat, the line voltage being about 58. As the limit of capacity of the lamp bank used was about 50 amperes at 50 volts, a reasonably large load for the larger sizes of meters was obtained by connecting several fans in circuit.

The indicating wattmeter used was a General Electric standard station instrument.

Two hundred and seventy-seven tests were made in all. The above curves show the performance of the 10-ampere 50-volt and the 25-ampere 50-volt meters.

After having obtained such curves for all the meters, the question arose as to what might be called the "average error of a meter." Evidently this is not always the arithmetical average of the errors at the several loads for which the meters are tested. If a meter operates half the time on full load and half the time on one lamp, the errors being say 10 per cent. for one lamp and 1 per cent. for full load, the error in registering will not be $5\frac{1}{2}$ per cent., but will be more nearly that for the full load, as the energy measured with the full load error of the instrument in play is much greater than the energy measured during the burning of one lamp. To make the effective error $5\frac{1}{2}$ per cent., it would be necessary to operate at a load of one light a much longer time, the times being inversely proportionate to the loads on the meter.

The true average error depends upon the ratio of the average load carried by the meter to its full load. By examining the record of sales for a sufficient period back it was found that the average operative load on the meters tested, for all seasons, was not far from half the rated load. Accordingly the "average results" were calculated on this basis by the following rule:

Multiply the error for each load by the number of lamps composing that load; divide the sum of these products by the sum of the separate loads.

This gave the effective average error, or that which was the ultimate outcome of the meter inaccuracies when transferred to the company's ledger.

The following results were found:

No. of meters tested.	Size of meter Volts	Amperes	Average error % Slow	Average error after adjustment; in %
6	50	50	15.4	.3 slow.
6	100	50	12.3	correct.
1	150	50	27.6	correct.
2	300	50	32.0	correct.
3	5	100	11.2	1.3 fast.
2	10	100	8.4	1.0 slow.
3	25	110	11.6	1.7 slow.
1	50	100		correct.
2	50	110		correct.
1	15	100	11.0	

Average error of all adjusted meters .22 per cent. slow.

This was certainly a very poor showing. The example of a 300-light meter over 30 per cent. slow shows what neglect and ignorance may do. No excessively bad values were admitted into this table. Meters which persisted in not running or in stopping, or in indulging in any other idiosyncrasies such as are peculiar to their class were consigned to the repair shop without further attention. The results represent the actual condition of the company's working meter system, and it is to be feared, the condition of a great many companies of its kind. The odium of such a condition is not to be placed wholly on the meters, but principally upon the unintelligent care given them.

As a result of the tests, the following recommendations were adopted. Another season will prove their value, and will show also whether the ordinary meter can be relied upon to retain its accuracy:

1. All meters should be tested and, if necessary, adjusted, when purchased. One meter was found to have an incorrect constant printed on its dial; an error which the ledger proved to have cost the company about \$250.
2. Every meter in service should be securely sealed and kept so.
3. A test or at least a short trial of the speed on several loads should be made when each meter is installed.
4. More attention should be paid to fusing the meters down to a safe limit; 20 out of 300 is too large a percentage of burnt meters in active service.
5. Periodical cleaning of the commutators and brushes by the indexer or wireman should be insisted upon. A dust-proof meter is a desideratum.
6. Every meter should be removed and tested at least once a year.

Such suggestions as the above will seem trite and commonplace to the manager of the modern station, with its well-planned economies and thoroughly organized testing department; but in view of the results obtained in the above tests it is

fair to assume that these are the matters that are being disregarded, with a certainty of large losses by the majority of small and struggling electric companies.

Electricity in Baltimore.—Notes from the Field.

BY C. B. FAIRCHILD.

ELECTRIC LIGHTING PLANTS.

THREE companies control the electric lighting interests of Baltimore, and for some time there has been a lively rate war, and in addition to this rate war all the companies, as well as the street railway companies, have been engaged in defending their interests in the local council against the strong efforts which have been made to force all the electrical companies to put their wires underground, and into subways built and controlled by the municipality. Fortunately for the companies there has come a deadlock between the two boards of the city government, so that the matter will probably rest for a time. Neither the lighting nor the railway companies object seriously to putting their wires underground, but they claim the privilege of locating and constructing their own subways; this is especially the case with street railway companies, for otherwise they would be required to put their wires into subways not on the line of their tracks, and in many cases into too close proximity to the high-tension currents of the lighting plants. The outcome of the movement will be watched with interest, for if it carries for municipal ownership it will doubtless suggest similar action on the part of authorities of other cities.

THE BRUSH ELECTRIC COMPANY.

This company was the first to install an electric lighting system in this city, having begun its operations in 1881. It still maintains the precedence in output over all the other competitors, as its plant is equipped with engines and generators of more modern design, due, no doubt, to a fire, which, in 1893, destroyed the old station and all the apparatus.

The control of the company is under a board, of which George Westinghouse, Jr., is president, G. H. Blaxter, of Pittsburgh, is manager, and E. F. Baker, local superintendent. The Brush series arc system of street illumination is employed, and the latest Brush-Adams lamp is supplied to new customers. The present city contracts amount to 791 lamps, and there are 1,589 commercial lights. The latest five-year contracts are for city lights 35 cents for all-night service, there being no moonlight schedule, and for the commercial lights the rate is 20 cents for a half night and 35 cents for all-night service. The old prices, before the rate war, were 30 and 50 cents. The constant current direct current arc light capacity of the station is 1,800 lights, while the constant potential A. C. arc light capacity is about 1,100 lights.

The present incandescent output is 38,000 16 c. p. lights. About 600 h. p. is furnished for operating small motors, for running elevators, pumps, etc., from a 220-volt system.

The station is located on East Monument street, and is a substantial fireproof building. The engine room is 130 feet square, and the floor space is 30 feet to the steel truss which supports the roof, there being no posts. The roof construction was put up by the Berlin Iron Bridge Company, and the metallic sheeting is lined by a non-condensing material supplied by the same company. The truss construction is of sufficient strength to support a load of 20,000 pounds at any point, making a safe anchorage for the hoists, by means of which the machinery is put in place. The floor is of cement. There are four subways, cement lined. The boiler room is 82x125 feet, with steel truss roof, and a steel structure over one-half for supporting coal bunkers, which are of metal, and have a capacity of 1,500 tons. The feed water heaters are also on this elevated structure, leaving large space in the boiler room proper.

The fuel is Cumberland "run of mine" coal and is delivered on cars, which run directly into the fire room and dump the coal into bins beneath the track, from which it is elevated to the fire floor, or to the storage bins, as the case may be. At present a supply of 700 tons is stored in the fire room, the automatic coaling device not yet being in operation.

The steam is generated in six 500 h. p. vertical water tube boilers of the Climax type, manufactured by the Clonbrock Steam Boiler Company, of Brooklyn, N. Y. The boiler shells are about 15 feet in diameter and 35 feet in height, and each has four fire doors; the average steam pressure is 160 pounds.

There are two stacks, one of brick and one of riveted steel plates; the latter is 175 feet in height, and has no guy wires, being built funnel shape at the base and brick lined to the height of 80 feet. The auxiliary equipment consists of Knowles pumps and Berryman heaters.

The chief interest of the station, however, centres in the engine room, and about the large units employed for generating the current for the incandescent service, and in a \$20,000 switchboard.

There are three incandescent direct coupled units, with a fourth being installed, each of which consists of a 1,000 h. p. Westinghouse steeple compound engine running at 205 revolutions, and a Westinghouse constant potential alternating current dynamo, with a rating of 750 k. w., and which is run under a tension of 2,800 volts. These generators are virtually double machines, there being two rings of fields having 36 poles and two armatures mounted on the same shaft to one side of the fly wheel, one being shifted ahead to the quarter phase position. The peripheral speed of the armatures is about a mile a minute.

Each half of the machine is run independent of the other, and the leads from the armature coils are led out through the hollow shaft, and connected to a four-ring collector, which is at the end of the shaft, overhanging the outside bearing, like an overhanging pulley, the rings being about 20 inches in diameter. The leads from the armature are connected to the alternate rings, thus relieving the strain that would naturally come on the insulation. From the collector brushes, which are set quaterning to each other, the leads are carried to a fuse box on the machine, then into the subway and out to the switchboards. The conductors, from each armature, consist of Standard underground lead-covered cables, and beside them are the (field) wires, consisting of Standard underground duplex cables, which, after passing through the field switch, pass to the switchboard, on the same brackets as the others. The fields are excited from a 220-volt machine, driven by an independent engine. These generators are designed for a two-phase relation, but are not so run at present. It is interesting to note, in this connection, that these engines and generators were part of the Westinghouse World's Fair exhibit at Chicago. In the opinion of the superintendent, a saving of at least \$300 per week is made in wages in favor of large units over those of small capacity for the same service. And again, the machines, all being over-designed, as compared with the engine power, they cannot be injured by an overload. This insures light repairs, and in the case of the present machines only one field and one armature coil has been lost in the four years' service.

DIRECT CURRENT.

The power for this department is generated by six Westinghouse compound engines of 300 h. p. each and two 125 h. p. engines of the same type for running the exciters. The engines are located in irregular groups about the room, and in some cases each engine drives six generators by means of tandem belts, three from each flywheel. The generators consist of two direct coupled 75 k. w. machines and one 280 k. w. belted machine, both of which are of the Westinghouse type, and generate the current for exciting the fields of the large alternators and such other machines as require it. The arc light machines consist of 18 old type Brush machines, all of 60-light capacity. There are also three 80-light and one 125-light Brush machines, five 75-light Westinghouse, the latter of which are excited from the 220-volt exciters, as noted above. The old Brush machines have been changed to self-oilers since they were first installed. All the wires from the arc machines pass into the subways and from this to the arc switchboard, which is on the main floor, but at some distance from the main alternating current switchboard. The arc board is made of brown polished marble, trimmed with brass, and with sufficient plugs to accommodate 26 machine terminals and as many more circuits. The plugged receptacles are of an improved type, making four surface contacts on the plug.

MAIN SWITCHBOARD.

This is located on the street side of the main floor, and is of polished white marble, 20 feet in height, and built in two steps, or rather the upper half is set back, making a gallery in front. The lower section consists of 16 panels and the upper of 20 panels. The instruments are covered with frameless plate glass cases, which, together with the polished brass and trimmings, give to the board a very artistic appearance. The lower section

is divided at the middle, and that on the right contains the instruments for the constant potential direct current machines and their feeder panels, as well as the dynamo panels. The left side is exclusively for the constant potential alternating current dynamo feeders. The upper gallery is entirely occupied by alternating current feeder panels. Each panel is numbered to correspond with the feeder which it controls, and represents a feeder or reserve panel, and has the following instruments, beginning at the top: Three Wurts non-arcing lightning arresters, in series (this being required because of the high voltage of the machines), a converter and compensator, a pilot lamp, a voltmeter and ammeter, two plug sections, a changing switch (double throw), two more plug sections, a Stillwell regulator and two fuse blocks.

The plugs on each panel are so arranged as to make it impossible to so connect them as to short circuit the machines. This is accomplished by having the holes of the positive and negative connections of different sizes and the plugs so designed that they will only fit into their appropriate holes. The voltmeters are so designed by a peculiar method of winding as to read the voltage at the centre of distribution of each feeder. This is done in order to compensate for line losses, giving a constant potential to each consumer. As an auxiliary equipment, Stillwell regulators or converters are provided, which are designed to raise or lower the voltage 10 per cent., according to the requirements, a switch being provided for reversing the current in the primary coils.

There are many other interesting features connected with the instruments and the wiring of the switchboard, but it will require too much space to detail them in this connection. The maze of wires is so systematically arranged and numbered that although at first they seem bewildering, they are really very simple, and the board is readily manipulated by one expert attendant and a boy helper. All the cables, after leaving the switchboard, go again to the subway and pass under the side-walks in front of the station, where they are led up the side of two large poles and out to the distributing arms, from which they branch out to the various circuits on their mission of bringing electric energy for lighting the streets, stores and houses, and for giving heat or power, according to the demand.

THE EDISON ELECTRIC ILLUMINATING COMPANY.

This is one of the early companies to undertake electric lighting in Baltimore, or, rather, it is a successor of one of the pioneer companies, which has been known under the successive names of the International Electric Telegraph and Power Company, the Fort Wayne Company and the Maryland Electric Company, the change of name coming with the change of ownership. The affairs of the company are now in the hands of Boston parties, Mr. A. A. Gassir being president and D. P. Robinson, local general manager. The plant is located on Pratt street, near Penn, and, like many other of the early stations, has been added to from time to time as business has demanded, and according to the peculiar ideas of the various managers, and now presents a remarkable combination of engines and generators, there being 13 of the former and a bewildering number and types of the latter.

The building is of brick and iron, and the engine room is divided into two parts, known as the old and the new. The former is 180x60 feet and 19 feet to the truss plates. The machines are crowded very closely together. On one side of the old engine room is a long countershaft operated at either end by a 750 h. p. Ball cross compound engine, and from this shaft, by means of a belt, are driven 11 80-light Wood machines, each pulley being provided with a friction clutch, by means of which it may be thrown in or out of action. On a line with the main shaft is a third engine of 200 h. p. of the Russell type, which drives, by means of a short countershaft, four 80-light machines and two old-type T. H. generators. The opposite side of the room is occupied by six engines, placed very close together, of various makes and designs, including a Russell, Ball, Ideal, Buckeye and Harrisburg, and both single and of cross and tandem compound types, and rated from 150 to 300 h. p. The first, or No. 4 engine, is belted to three 80-light Wood machines, while each of the others drives a single multipolar generator for incandescent lighting. Some of these are of the Slattery and others of the General Electric type, having a capacity from 1,500 to 3,000 lights.

In the new engine room No. 10 engine occupies the end of the floor, and is a tandem compound Porter Allen machine

of 550 h. p., and runs at 200 revolutions per minute. This drives from two fly-wheels one large M. P. 6,000-light generator of General Electric manufacture and a 260-light constant current machine. The remaining three engines are of the Ball type, from 250 to 300 h. p., and drive several 80-light Wood machines supplying 225 lights, together with two General Electric M. P. generators for power purposes, the latter of which runs at a tension of 250 volts. The arc light circuits supply 4,160 lights, of which 675 are for the city service, the balance on commercial circuits. One daylight circuit provides for lighting the post-office and one or two other buildings.

Two types of arc lighting are employed, some of the Adams-Bagnall, others of the General Electric type. Many of the latter are of the enclosed or double globe type, and are run two in series, but are so connected that either one can be cut out without interfering with the other. A lamp repairing department is located on a gallery overlooking the large engine room, where all lamps are tested and necessary repairs made. The exhaust pipes of the engines and the leads from the generators occupy subways under the floor; the latter come up to the switchboards, of which there are two, one on the gallery in the partition between the two rooms, and the other along the front of the building. These are of marble and are equipped with General Electric instruments. The wires go from these up through the skylight out over suitable racks, there being 26 circuits.

Thirteen boilers furnish the steam, eleven of which are of the Campbell & Zell water tube safety type, and two are of the Babcock & Wilcox make, having an aggregate of 400 h. p., and are so coupled that any desired combination of steam pipes can be obtained. Two batteries of each type of boilers are provided with stokers of the Acme type; the others are fired by hand. The George's Creek coal is delivered in carts. There are four smokestacks, three 88 feet in height and one of 110 feet. There is the usual auxiliary equipment of feed water heaters of the National Excelsior type. For cleaning the boiler tubes the machine known as the Union Boiler Tube Cleaner is employed, and which has a capacity for cleaning 20 or more tubes a day. This is a rotary scraper, attached to an adjustable rod, which is moved in and out through the tube, and is driven by an endless rope from a pulley actuated by a small steam engine.

This station is neither to be criticised nor imitated. It is of value chiefly to show how electric lighting stations should not be built, and yet it is operated with a considerable degree of economy. It is soon to be superseded, however, by a new plant with modern equipment. The site for this has already been secured and plans and specifications have been prepared.

Transformer Economy.¹

BY PROF. W. E. GOLDSBOROUGH.

A GREAT deal has been said and written about the static transformer of alternating currents, and yet we are only just beginning to understand this much discussed piece of apparatus. The manufacturers have made it and experimented with it, the theorists have experimented with it and disputed over it, the underwriters have disputed over it and endured it, and the central station men have endured it and made use of it to the great good and comfort of the public. No other piece of apparatus in the field of electrical engineering has been lauded higher or been the subject of greater abuse, and to all it has served a purpose.

To-day the transformer occupies a higher position than ever before, and it grows in importance as each new development in the field of applied electricity points out a new department of usefulness for it.

With a view to investigating the present status of the transformer and the ability of transformer manufacturers to meet

¹Abstract of a paper read before the N. E. L. A., Chicago, June, 1898.

in all cases the exacting specifications which they have laid down for themselves, I have had a number of transformers of recent design tested in the Purdue laboratories within the last year.

A 2.5 kilowatt transformer was submitted for test that was guaranteed to conform to or improve upon the following specifications: Core loss 48 watts, regulation 2.1 per cent., and full load efficiency 96.1 per cent. The test of this transformer gave, core loss 42.19 watts, regulation 1.9 per cent., full load efficiency 96.2 per cent.

The showing made by this transformer is good. The core loss is 5.81 watts less than the stipulated value, and the efficiencies are in excess of the stipulated values. In this case the manufacturers more than substantiated their guarantee, and supplied a transformer that is a greater revenue producer than the specifications call for. If the core iron of this transformer can be relied upon as not materially increasing in its hysteretic loss with age, it is an easy matter to figure the money value of the excess economy that the transformer develops.

Suppose, for instance, a contract should be made for 40 of these transformers at \$30 each to meet an increase in a station load of 100 kilowatts. On an all-day schedule these transformers would probably carry a commercial load equivalent to full load working for five hours. This assumption may seem to represent a better condition of service than is usually met with in practice, but it is an assumption that is fair to the manufacturer in considering the all-day efficiency. The transformers would therefore be working under no load for 6,935 hours and under full load for 1,825 hours per year, and under the conditions of the test would save 1,794 kilowatt hours to the station. If we figure the cost of producing this power at 2 cents per kilowatt hour, the saving per year would be \$35.88 for the forty transformers, or practically 3 per cent. on the amount invested in the transformers. If this power were sold for 6 cents per kilowatt hour it would represent a net gain to the purchaser of $1,794 \times 0.06 = \$107.64$ per year more than he had any right to expect under the contract specifications. Another similar test was cited which gave about the same results as the first one subjected to a test.

Suppose we estimate the economy of transformers of this type just as we did those of the type previously considered. The 40 transformers, working on the same schedule, would waste 4,014 kilowatt hours more power than they should under the specifications advertised. At 2 cents per kilowatt hour the total money loss would be \$80 per year, or over 6.5 per cent. of the cost price of \$1,200.

But these examples do not cover the ground. I will cite two others. In the case of a 15 kilowatt oil insulated transformer, guaranteed to develop a quarter load efficiency of 96 per cent., a full load efficiency of 97.4 per cent. and to have a regulation of 1.77 per cent., the test showed a quarter load efficiency of 94.5 per cent., a full load efficiency of 96.1 per cent., and a regulation of 1.6 per cent. The core loss of this transformer, which operates at 60 cycles, is 186.6 watts, and the specifications under which it was built require that the core loss should be about 150 watts.

It would take seven of these to give an output of 100 kilowatts—and they would cost not less than \$115 each. The seven transformers in this case would waste 3,855 kilowatt hours in a year, which represents a financial loss of \$77 in one year, over and above the loss to be expected. This approximates 10 per cent. of the original cost of the transformers and is an item that cannot be neglected. If, on the other hand, this waste power could be sold at 6 cents per kilowatt hour, it would represent a part of the just return on the investment contemplated when the transformers were purchased, and would mean \$221 to the company.

I do not claim that the figures which I present to you cover all the items of expense that enter into the installation of 100 kilowatts—in transformers. They do not, but they do represent a phase of the question that deserves more than passing attention at a time when competition is becoming sharper and sharper.

In what I have so far said I have not touched upon the matter of the ageing of the transformer core-iron. In cases where it is appreciable it only serves to aggravate the conditions, and make the percentage loss greater. In the same way the cost of production and the selling price of the power both enter as important factors, as well as the cost of the transformers. All of these assumptions I have placed low and they should be re-

garded rather as pertinent examples of the conditions that exist in large plants. The small plants will be affected by influences of this character to a much greater extent.

I do not wish to tire you with figures, but as I believe you will be interested in these comparisons of guaranteed and actual efficiencies, I wish to call your attention to one more case before leaving this matter. Not long ago a manufacturing company requested permission to send a 1 kilowatt transformer to the university laboratories for a special test, as the transformer was of a new type and highly efficient. There was no direct guarantee in this case, but the impression was given that the transformer would develop an efficiency equal to, if not exceeding, the efficiency of any other transformer of like capacity on the market. The results of our tests indicated a core loss in a 1 k. w. transformer of 178 watts, a full load efficiency of 83.6, a quarter load efficiency of 62.4 and an all-day efficiency of only 54.5 per cent.

As regards the ageing of the modern transformer irons, I hold rather a conservative opinion at the present time. A great deal has undoubtedly been accomplished within the last few years in the way of improvement in this respect and the modern transformers that are supplied to us for testing show a wonderful gain in efficiency, due both to the lower initial core losses and to the diminished per cent. of increase of these core losses with the ageing of the iron.

The general opinion seems to prevail at present to the effect that ageing is due directly to the reversal of the direction of the flow of the magnetic flux in, rather than to long continued heating of, the iron forming the cores of transformers, and this opinion is also expressed in much of the printed matter that has come into my hands.

The fact seems to be well established that non-ageing transformer iron is a commercial possibility, but the fact remains to be demonstrated practically that material of the necessary quality can be obtained in sufficiently large quantities to supply the demands that are being made upon the manufactories.

Failure in this regard is not the fault of the builders of the transformers and I have reason to know that there are cases in which disquiet prevails in the minds of managers as to whether or not they are getting what they are paying for. I know that the general claim is made that iron with an "inappreciable ageing effect" is used, and I do not wish to go on record as claiming that it is not used, but what I do wish to point out is that there are transformers being placed on the market to-day that do not contain non-ageing iron. From a large transformer company I have received notice that "at the present time we have not non-ageing iron which will fulfill our specifications of core loss; that which we have on hand will give a core loss of from 20 per cent. to 25 per cent. greater than the amount stated in our specifications." At the present time, therefore, it is needful to make just as careful tests for ageing as for efficiency or for insulation, in spite of the fact that the former take a longer time and are therefore relatively more expensive to make.

During the last three months six transformers of different types have been subjected to more carefully conducted ageing tests in our laboratories. The completed report on these tests has come to me within the last few days and I can give you a resumé of the results.

The core losses of transformers A and B were high to begin with, the first being 72 watts and the latter 83 watts. The per cent. increase in the core loss of these two transformers does not, however, seem to be as great as the per cent. increase in the core losses of transformers C and D that are of more recent manufacture, and that showed initial core losses of 31.5 and 37 watts respectively.

Transformers B and D are of 1.5 kilowatt capacity and transformers A and C of 2.5 kilowatt capacity. An increase of from 5 to 10 per cent. is shown in all the transformers.

To get an idea of what this means suppose we consider the effect upon the economy of the 2.5 kilowatt transformers, considered in the second case discussed above of a 10 per cent. increase in the core loss. It will add \$1.11 per year to the cost of operating each transformer at 2 cents per kilowatt hour, or \$44.4 for the total number.

This represents an additional gain of 3.7 per cent. per year on the investment in three months, or a possible percentage loss on the investment of 14.8 per cent., after the first year, on the supposition of a uniform increase in the core loss.

These figures are not startling in any way; they are too small for that, but they are matters of fact to be taken into consideration when making investments. The opinions that I am voicing regarding the ageing of modern transformer irons are conservative, as I believe the transformers built to-day will show a marked improvement upon the performance of transformers built even as late as one year ago. As far as the ageing tests that we have made go to throw light upon the subject, I am inclined to believe that the ageing problem has as yet not been solved, as none of the transformers tested have met the requirements of the specifications under which they were submitted, and some have fallen very far short of it. All of the transformers tested were new except transformer A, which at the time these tests began had a core loss already increased to 13 per cent. above its initial value. Transformer A was built about two years ago.

The ageing of transformer iron does not increase at a constant rate with the time. The rate of increase diminishes as the service continues, but the increase may go on indefinitely. Until the use of non-ageing iron becomes more generally possible than at present, it is probable that it will pay to replace the majority of the transformers placed on the market by new ones every few years.

The correct insulation of transformers is another important point that should be considered by the central station manager. Like many of the problems with which we have to deal in the effort to make the transformer a commercial success, this one seems to be subject to a wide variety of opinion. The oil insulation of transformers has deservedly come into great favor, and where care is taken in the selection of the oils used and in the proper design of the transformer case, high protection is secured. Oil insulation under all circumstances does not, however, secure to the purchaser the protection which he feels he is paying for. The claims that are usually made for the superiority of oil insulation, to-wit, that it serves to preserve the insulation from oxidation, reinforces the resistance of the insulation to puncture, reinsulates punctures after the passage of the discharge and facilitates the diffusion of the energy liberated as heat in the core and the coils, can in general be readily substantiated.

My experience, however, is that these statements must be regarded as having only a relative bearing upon the subject. Under certain circumstances the insulating value of an oil will be very materially impaired. We are told that transformers will last indefinitely when insulated with oil, whereas without oil the insulation will be so deteriorated after five or ten years that the transformers should be placed, and it may therefore be a matter of surprise that the insulating qualities of the oil itself are ever seriously diminished. As a matter of fact experiment shows that the insulating properties of the oils commonly used in transformers are increased as their temperatures are raised up to about 110 degs. C., and that if allowed to cool they will not lose their augmented power of resisting a disruptive discharge. This much might be said in favor of oil insulation, in view of this two or three fold gain in insulating power, were it not for the fact that a continued heating of the oil for any considerable length of time changes the oil to such an extent that on being cooled its break-down value will be only about one-fifth of its original value. And therefore an oil insulated transformer that will stand an insulation test of 10,000 volts when new, may break down under a pressure of 2,000 volts after having been in continuous service for a considerable time. Conditions such as will produce a result of this character are not likely to occur in the case of modern transformers, as the increase in the temperature of even the poorest transformers rarely exceeds 70 degs. C. I have, however, met with cases in which excessive heating has resulted when the transformers were kept continuously in service, and I have also in mind a case in which a good modern transformer was so situated above a tin roof and in a position where it was protected from any breeze that might be stirring, that, when the sun played upon it, its temperature reached perfectly distressing values.

What I have said will serve as a hint of how not to handle a transformer, and the importance of selecting proper places for the location of transformers.

If you will look carefully into the matter you will find that not all of the burn-outs are due to faulty construction on the part of the manufacturer. It is my experience that the contractor has been in fault in a fair proportion of the cases in which the transformer and service installation have suffered.

For all commercial purposes the best oils will be found to give thoroughly satisfactory results and retain their insulating properties unimpaired so long as the maximum temperature of the oil does not exceed 60 or 70 degs. centigrade. In making a station test of a transformer, if the rise in the temperature of the windings, as measured by the increase of resistance method, does not exceed 50 degs. centigrade, after a ten hours' run at full load, the transformer may be passed as satisfactory in this respect.

In connection with oil insulation it must be remembered that its efficiency as an insulating medium is impaired by discharges in the oil. One of the foremost claims made in behalf of oil insulation is that it will flow in and fill up a rupture in the insulation of the coils. Every electric discharge that takes place through the oil, however, disintegrates and breaks up the normal structure of the oil, and causes carbon and other conducting compounds to form. These will rapidly multiply if the discharges are at all frequent, and will destroy the insulating properties of the oil.

There has been a great deal of interest expressed recently in the effort to formulate a definite set of specifications covering the construction and insulation of transformers, with the end in view of decreasing the fire hazard and supplying the necessary protection from loss of life and property to both the producer and consumer of electrical energy.

I have read a great many articles for and against the use of earthing devices, grounded shields and grounded secondaries, but I am yet to be convinced that the prominent American practice of high insulation resistance to a disruptive discharge and a plentiful use of well-grounded short air-gap lightning arresters, does not give a sufficiently good protection.

As I have already remarked, the number of modern transformers that are reported as burning out is relatively very small. By far the greater portion of the troubles arise from crosses between the high and low potential circuits, and in such cases the loss must be attributed to faulty installation and not to any imperfection in the transformer.

An oil insulated transformer for use on 2,500-volt primary circuits, or less, having a maximum temperature at full load not exceeding 65 degs. C. and designed to stand an insulation test without oil of 7,500 volts for five minutes, and a prolonged test of 10,000 volts with oil, will be in slight danger from lightning discharges if protected within a distance of 500 feet by a properly installed lightning arrester.

A transformer should also be able to stand a double primary potential test for five minutes, and the insulation test should be made between the coils and between each coil and the core.

In the discussion which followed the reading of this paper, Mr. Layman pointed out the necessity of having the central station man and the manufacturer work hand in hand in their attempt to produce an efficient transformer.

Mr. Thayer discussed the advisability of constructing transformers suitable for operating lamps at different hours in the day. He also stated that he had never lost a modern transformer by lightning.

Mr. Wurts then discussed at length the effect of lightning when it strikes a line, with special reference to the theory of surging of the static charge. He explained the modern meaning of short air-gap lightning arresters and how to measure the resistance of a lightning arrester, as follows:

Connect in shunt to the lightning arrester a variable spark gap, and then send disruptive discharges through these paths in parallel, one of them being the lightning arrester and the other being a variable spark gap. If the latter is closed the disrupted discharge will pass through the so-called gap. Gradually the disruptive discharges passing at intervals, open the spark gap until the discharge passes either through the arrester or the spark gap. You will reach a point where the discharges will divide, sometimes going one way and sometimes going the other. It is difficult to balance them. The length of the variable spark gap I consider a measure under these conditions of the resistance which that particular lightning arrester offers to the passage of disruptive discharges. In making measurements of that kind, between the lightning arrester referred to, having a spark gap and a resistance in series with that spark gap, in making a comparison between that and the Westinghouse non-arcing lightning arresters, I find the arrester with a short gap had just three times the resistance which the Westinghouse lightning arrester had, which lightning arrester had three gaps; in other words, I could place three

of the Westinghouse lightning arresters in series and that series in shunt, and a single short-gap lightning arrester, and the discharges would sometimes pass one way and sometimes the other, verifying the test which I made in placing a single variable spark-gap in shunt with the short gap.

Mr. Wagner then gave some valuable data on the all-day efficiency of transformers and the placing of the cost of the transformer load as regards the central station. He stated in answer to Mr. Davis that the renewal of transformers depends on the condition of the line and the method of protection of the line, there being no reliable basis for estimating the life of transformers. The depreciation of a modern transformer would not be greater than 10 per cent.

Prof. Goldsborough, in answer to Mr. Walbank, gave additional information on the relative values of oil and air insulation and the ageing of transformers, stating that at present the age loss for a year will not be over 10 per cent.

Electricity on Board the Hospital Ship Relief.

THE Relief, the Government hospital ship, which was fitted out for service in Cuban waters, left the pier at East Ninth street, New York, last Saturday. The ship, which was bought a few weeks ago by the United States Government, was formerly a Sound steamer and was built three years ago. She is about 325 feet long and has now been transformed into the most perfect and spacious hospital ship which has ever gone into service. The hull of the ship is painted white, as are her spars; the only exterior touches of color about her are a narrow band of green along her sides, the red lining of the ventilators and the red cross and the American flag which she flies. In her interior fittings the Relief is a model of modern sanitary hospital equipment. Four hundred patients may be accommodated between her decks, and in an emergency nearly twice that number of beds can be set up.

The electrical equipment of the ship is very complete. The generating plant consists of two 15 k. w. G. E. marine type multipolar generators direct connected to two G. E. marine type vertical engines. The current is distributed from a main switchboard, containing two sets of ammeters and voltmeters, and one ammeter for registering the current used by the searchlight. On the switchboard are mounted the necessary switches for distribution of currents and those necessary for connecting the two machines in multiple. The ship is wired for 400 incandescent lamps, the wiring all being done in moldings, special marine "red core" Habirshaw wire being used throughout. Lead-covered wires are used for the wiring on the decks and promenades, and the lamps at these places are attached to steam and watertight sockets and are protected from the elements by wire screens. Besides these lights there are numerous portable disc lamps in the staterooms and wards, to which are attached long flexible cords and plugs, so that the medical attendants or officers may have a light at any convenient location. Then there are placed around the wards several theatre reflector lamps for use during an operation. These stands are each furnished with a powerful reflector and a cluster of six incandescent lights. The lamps in all the five wards have very ornamental globes, which are in perfect harmony with the handsome gold and white decorations throughout the ship. There are also several side and headlights around the hull of the ship so as to make its presence and mission known to all at night. To further insure this, as well as its own safety, a powerful G. E. searchlight has been mounted on the bridge, said to be of ten million c. p. and having an 18-inch projector. Perhaps the most interesting feature of the installations on this ship is the important part electricity plays in its medical equipment. The operating room, which is located on the main deck, is cooled by a number of 1-12 h. p. Lundell bracket fans, of which there are 65 on the ship, and several 1-6 h. p. ceiling fans, of which there are 25. A cauterizing apparatus operated by an electric motor and electric lights with reflectors complete the electrical equipment within the operating room. Complete X-ray outfits have been installed on the main deck right outside of the operating room, as they are too large to be placed inside. One of these sets was furnished by Otis, Clapp & Son, Providence, R. I., and consists of a large static machine driven by a ½ h. p. G. E. motor and giving a 12-inch spark. The other two outfits are of the well-known Thomson inductoriums, manufactured by the G. E. Company at Harrison, N. J. The coils are 14 inches long and receive current from five storage cells of 150 a. h. capacity, furnished by the Electric

Storage Battery Company, of Philadelphia. The coils give a 10-inch spark. A complete bell system is employed throughout the ship, as well as telephone apparatus, the latter manufactured by the Wilhelm Telephone Manufacturing Company, of Buffalo, N. Y. There has also been installed an automatic electric steam whistle, which can be operated from the bridge, and a 3 h. p. and a 2 h. p. Sturtevant exhaust fans on the main deck for carrying off the fumes from the engine room, as well as those from the following apparatus: A distilling plant, a carbonizing machine, which can furnish 2,000 gallons of soda water per day, a freezing plant, by which sea water can be converted into fresh ice, a disinfecting plant and a steam laundry. The entire electrical equipment was installed by Jos. Barre & Co., 25 Fulton street, New York, under the supervision of Mr. John P. Lund, assisted by Mr. T. A. Robinson and a large number of experienced wiremen.

A Statue of Franklin for Philadelphia.

IT is hard to believe that the city of Philadelphia is still without a statue of its great citizen, the statesman, author and philosopher, Benjamin Franklin, but such is the fact. We are glad to be able now to record the munificence of Mr. Justus C. Strawbridge, who is removing that reproach by presenting to Philadelphia a fine public statue of Dr. Franklin. Through his courtesy and that of Mr. John J. Boyle, the sculptor,

BOYLE'S STATUE OF BENJAMIN FRANKLIN FOR PHILADELPHIA, PA.

whom the commission has been entrusted, we present herewith a picture of the statue as exhibited recently in Mr. Boyle's studio, in the clay model. The statue when finished in bronze is to be set up in front of the postoffice, an appropriate situation, in the heart of the city and worthily occupied by a memorial to one who was the first Postmaster General of the United States.

Franklin is shown seated in a Colonial chair of the period, one hand resting on its arm, while the other hand holds a scroll of manuscript; and a book, to which probably some reference has just been made, stands against the legs of the chair. For the head, Mr. Boyle has adhered closely to the outlines of the well known Houdon bust, but has thrown into the features the best expression of the large-hearted and broadly-sympathetic man whose tastes made him also one of the most distinguished scientific investigators of his time, as well as one of the clearest thinkers and writers on political and economical subjects. The figure is dressed in ordinary small clothes, over which is worn the large, loose fur-trimmed surtout made familiar by the Duplessis portrait. The statue will not be visible from the rear, being backed against the granite of the postoffice building, which should throw the bronze into high relief. The best view will be had by passers-by on Chestnut street. This monument to one of the foremost founders of the Republic is a worthy addition to the National statuary.

Vol. XXVI. NEW YORK, JULY 7, 1898. No. 531.

Standardization of Electrical Apparatus and Nomenclature.

WHenever an art reaches that state of perfection, or has expanded to such an extent, that it demands standardization of its terms and apparatus, it becomes the duty of the practitioners to formulate for their own use and convenience standard rules, regulations and definitions. The necessity for such action had been felt for some time past by the manufacturers and buyers of electrical apparatus, when the A. I. E. E. finally took the matter in hand and appointed a committee who were to formulate definitions and standards based on modern practice which would serve as a guide to American electrical engineers in the construction and nomenclature of their apparatus.

That committee, composed of distinguished men, representing every branch of electrical engineering, who have for years enjoyed the confidence of the profession, have finished their important and delicate task and have submitted for the consideration of the members of the Institute and the profession in general their preliminary report on the standardization of apparatus. This report, which was submitted at the general meeting of the Institute held at Omaha is so thorough, complete and timely in every particular that we are assured of its cordial reception by every member of our profession. It embraces not alone suggestions as to the standardization of the sizes of apparatus, but includes definitions of terms most frequently met with in plant specifications, as well as suggestions for standard methods of conducting and recording tests.

The first subject taken up by the committee for standardization and which occupies one-half of the report, is that of "efficiency." After defining this term, they suggest methods for measuring it as well as electrical and mechanical power, specifying the correct use of the terms designating the various electrical and mechanical losses. The next thing taken up under the general heading "Efficiency" is the commutating machines, including direct-current generators and motors, direct-current boosters, motor generators, dynamotors, converters and closed coil arc machines. Definitions of these machines are then given and their electrical, magnetic and mechanical losses and efficiency are fully discussed. Under the next subheading are included synchronous machines, treated similarly to the above; then come in the order given: Synchronous commutating machines, including (1) synchronous converters, i. e., converters from alternating to direct and vice versa, and (2) double-current generators, i. e., generators producing both direct and alternating currents. Rectifying machines or pulsating-current generators, including (1) open-coil arc machines, (2) constant-current rectifiers and (3) constant potential rectifiers. Stationary induction apparatus, including (1) transformers, compensators or auto-transformers, (2) potential regulators of the induction or magneto type, and (3) reac-

tion coils. Rotary induction apparatus, comprising induction motors, induction generators, frequency changers and rotary-phase transformers. Transmission lines, the efficiency of which is fully defined and a uniform measurement of it proposed. The next subject taken up for discussion is that of rise of temperature, wherein the highest permissible temperature of apparatus under various conditions is laid down, and how and where such temperature should be measured. The subject of insulation, which is the next to receive attention, is subdivided into insulation resistance and di-electric strength, valuable data being presented for the guidance of those dealing with high potential circuits and apparatus. Following this chapter is one on regulation, which includes definitions of the term as applied to all classes of electrical machinery; and appended to this chapter is one on variation and pulsation. The concluding chapter, namely, the one on rating, is one which will be welcomed by the student and layman alike, as it affords them a means for the correct and uniform designation of all apparatus, with respect to their voltages and frequencies. Appended to the report is a recommendation of a notation which has already become fairly well standardized by continual usage.

Such is the wide scope covered by the remarkable document prepared by the Institute committee, of which Dr. Francis B. Crocker is chairman, and the following are members: Drs. Cary T. Hutchinson and A. E. Kennelly and Messrs. John W. Lieb, Jr., Charles P. Steinmetz, Lewis B. Stillwell and Elihu Thomson. It is a report which should find acceptance not only on this side of the Atlantic, but receive the sanction of our cousins on the other side. It is of an international character covering the practice of modern electrical engineers in all countries. Standardization of machinery means nothing more nor less than uniformity of practice, which is its natural consequence. It resolves itself simply into a definition of the word "standardization," as meaning uniformity of practice and apparatus. Viewing standardization in this light, no one will deny that it is as flexible as uniformity and subject to the same conditions of change of practice. Both allow improvements to go on and will be of incalculable benefits to the profession by avoiding confusion, reducing cost and preventing delays. It is the number of so-called standards in use oftentimes in one country, and not the use of one standard, subject to change as the conditions of trade or advanced thought demand it, that has caused confusion and annoyance. This we trust will be avoided in the future by the adoption of the work of the standardizing committee.

Tests With an Induction Generator.

A VERY timely and interesting paper was the one describing the tests with an induction generator, read by A. F. McKissick at the general meeting of the A. I. E. E. at Omaha. Its great value lay in the fact that it contained experimental data and curves which verified previous suggestions made by Mr. Steinmetz and thus placed the induction generator on a definite basis. While the extensive employment of the induction generator is still a matter for speculation it possesses such admirable qualities as to make it well worthy of the attention of electrical engineers. It was Mr. Steinmetz who pointed out that the induction generator must necessarily have as a load a circuit of leading current. But when the conditions are such that it can be used, the induction generator has the great advantage of the absolute absence of continuous current exciting circuits, collector rings, or any other parts requiring attention. The voltage, he continued, is generated in a stationary structure, and the revolving part is a solid structure of iron and copper bars. Furthermore, as soon as the circuit is opened or short-circuited, the power is gone and the machine is dead, so that it is a type of alternator requiring no attention whatever. Besides it can be run at different speeds and still the same frequency can be obtained from it. Comparing the induction motor curves with those of the induction generator the peculiar feature is brought out that the same machine as an induction generator gives a considerably larger output electrically than as an induction motor mechanically. All these points were carefully tested and verified by Mr. McKissick, whose curves and data will have a permanent value.

He also verified the suggestion of Mr. Kelly that the induction generator can be advantageously used as a booster, being a machine with no brushes, collector rings or commutator. The author of the paper also pointed out the advantage which could be taken of the induction motor when used for the propulsion of street cars, acting as a generator in descending grades, pumping

back energy into the line, doing away with braking to a great extent. And thus not only has the value of the induction generator been demonstrated, but also the fact again that patient experimenting tending to a definite end will always leave a lasting impression on the progress of an art.

Bell Telephones In Use.

IT is worthy of note that according to the June monthly return of the American Bell Telephone Company the number of their instruments in use has crossed the 1,000,000 mark, showing there to be not far short of a half a million Bell telephone subscribers in this country, and a gain of 85,000 subscribers since June, 1897, as the gain in instruments in that period has been 170,997. This must be admitted to be an enormous gain, the total number of instruments outstanding being 1,012,159 on June 20, as compared with 841,162 a year ago. Yet had the same annual gain been made during the past twenty years, the Bell Company would now have 1,750,000, and the pasture for the new independent companies to graze on would have been correspondingly limited. It is early to determine any average or proportion of telephones to population in the United States, but there has certainly been a much nearer approximation to it the last year or two than ever before, as the result of the great stimulus to the industry given by what is known as the "independent" movement. Some of the rates quoted by these new concerns are amazingly low, but the mortality among the enterprises launched with such apparent recklessness has not yet been high by any means. It would be interesting to have their figures of net gain in subscribers as compared with the Bell during the past year. We should estimate it as fully equal, making an increase of 150,000 telephone subscribers for the whole country for 1897. Moreover, most of these have been gathered in from relatively small communities. There is no "opposition" in New York, Brooklyn, Philadelphia, Boston, Chicago and several other large cities, where the outcry against high charges has been loudest. Signs of it have not been wanting, of course, but the lack of it is due probably to the general satisfaction of the public with the service and the difficulty or expense of putting in a new system, with underground wires, able to compete with the service already entrenched and organized.

As things are, every indication points to a more rapid telephone growth than ever, and to success in the field based rather upon merits of apparatus and service than upon patents merely, or other passing influences of that nature. The public values the telephone highly, and is coming to depend upon it, and, having acquired the telephone habit, may be trusted to increase its patronage of the system at a growing ratio.

Women Car Conductors.

IN some parts of South America it has long been the custom to employ women as conductors on the street cars. The practice has now been taken up in this country by the Chillicothe, O., Electric Railroad, Light and Power Company, from whose president, W. J. Myers, we have quite a cheery letter on the subject. He says: "We could not afford to employ men, and we could not see why women would not make as good conductors as men. We keep them on duty ten hours per day and pay them \$4 per week; and they are proving themselves in every way competent and efficient. We were very particular in selecting them and had no trouble in getting good applications, and a great many more than we are able to employ. It gives us a very clean service and we think that this will be a new field for the employment of ladies." This is certainly an encouraging outlook for those who wish to see the sphere of woman's work enlarged; but we confess that to our way of thinking there are nicer employments for women than running the fare end of the street car business. We are not familiar with the characteristics of the people of Chillicothe, but the men are probably gallant enough to do all they can to assist the women in their work, and render it as easy and light as possible. Outside of Chillicothe it might be different, for the burdens of conductorship in large cities are by no means small. It will be interesting to see how the Chillicothe experiment works out. If the Spaniards insist that we shall wipe them bodily off the face of the earth before they quit fighting, we may need more women conductors and perhaps some women "motorneers."

THE war taxes are now being imposed and their collection appears to be going along very smoothly. No one likes to be taxed, and the readiness with which the new burdens are assumed must be taken as another proof of the strength of the national feeling that is behind the Government in the war with Spain. The special one-cent telegraph and telephone taxes have been arranged for without difficulty. The telegraph companies have left it to their customers to put on the penny stamp, and while one hears some sharp words about this action, generally it is quietly acquiesced in. In New York City the local telephone company has wisely made its long proposed reduction of tolls coincide with the imposition of the tax, so that the 15-cent message is now 10 cents, and no one is a bit the worse off except the Government, and the amount that the Government loses is too small to worry about. In other parts of the country the telephone exchanges are for the present apparently leaving their rates unchanged and paying the one cent themselves.

THE Omaha meeting of the American Institute of Electrical Engineers, which was held last week, was worthy of that society. Having met in the far East in 1897, it was only fit and proper that the Institute should go West this year, even if the prospect of a good attendance was small. The programme of papers was admirable, and in solidity and real value the contributions would be hard to surpass. Attention is directed to some of the papers in this issue, and it will be gathered that the Institute, under Dr. Kennelly, promises to be more useful than ever to the profession at large.

INDEPENDENT telephony, as it is called, is still young, but it is vigorous and growing. It appears to find some difficulty in reaching the "convention" stage, but the rather slim meeting in Chicago last week is expected to be followed by a much larger one in September or October. The effort of those interested in independent telephony to square it with actual conditions and problems is seen in the various changes to the constitution which was drawn up only a year ago at Detroit and which committed the association to a programme involving no slight difficulty in its successful accomplishment.

Mrs. Charles E. Newton.

A great many in the electrical field will regret to learn of the death from pneumonia of Mrs. Alice Huntington, wife of Mr. Charles E. Newton, secretary of the Jewell Belting Company, of Hartford, Conn. She was the daughter of Prof. Charles W. Huntington and an active member of the Baptist Asylum Avenue Church. She leaves three children. The sympathy of a large circle of friends is extended to the bereaved husband and family.

Ward—Clarke.

The "war weddings" are quite numerous and interesting. Mrs. Edith Wigham Clarke, of this city, was married at Chattanooga, Tenn., a few days ago to Major George Gray Ward, chief surgeon of the Twelfth Regiment. She is the daughter of the late Thomas M. Wigham, who was a partner in the well-known Wall street banking firm of Jacob Little & Co. She is a very popular society woman, one of the organizers of the Badminton Club, and Dr. Ward is a well-known physician of this city. He is the son of Vice-President Ward, of the Commercial Cable Company, and was born in London about thirty-one years ago. The first public announcement of the engagement was made on April 1. It was intended to have the ceremony in this city after Dr. Ward's return from the front. Dr. Ward, however, insisted that the wedding take place without delay, as his regiment is one that has been ordered into active service.

Practical Features of Telephone Work.—XVI.

BY A. E. DOBBS.

THE INDUCTION COIL.

THE purpose of the induction coil is to raise the battery power of the one or two cells used for the transmitter of from 1.5 to 3 volts, to a much higher pressure, in order to overcome the resistance of long lines. A small amount of current at a high pressure will do the same amount of work as a larger current at a lower pressure, exactly as a transformer does in electric lighting. For example, in long distance power transmission by alternating currents the pressure is from 10,000 to 30,000 volts. Now, no machine would be safe at this terrific pressure. Instead then of generating this high pressure the machine delivers a powerful current at a pressure not to exceed 3,000 volts, and more frequently 300 when it is changed or stepped up, by means of a transformer. This is simply a form of induction coil, wound to give the necessary voltage (pressure) for long distance transmission, and the current is transformed back again to 100 or 500 volts for lighting and power at the other end. Thus we see that the same kind of an induction coil (transformer) can be used to step the current either up or down, as may be required.

This stepping up and down always increases or decreases the quantity of current in inverse ratio to the voltage, minus, of

FIG. 48.

course, a small amount lost in transformation. Thus a transformer, whose ratio is 20 to 1, which is commonly used in electric lighting, may take in a current of only 10 amperes on one side, at a pressure of 2,000 volts, coming out on the other side at a pressure of only 100 volts, while the current has risen from 10 amperes to nearly 200.

All induction coils and transformers will work either way; first, to raise the pressure and decrease the current; or, second, to raise the current and decrease the pressure, as shown in Fig. 48, and it will be noticed by a comparison of the lines that the power remains the same in both cases. That is, theoretically, practically there is a loss of from 3 to 50 per cent. Telephone induction coils, wound to a proportion of 500 to 1, which is commonly used with the Blake transmitter, will raise the battery current to more than 1,000 volts, but the quantity of current has become so small and the alternations are so rapid that it cannot be felt if taken through the body; because at this ratio a current of 1 ampere in the primary circuit becomes less than .05 of an ampere in the secondary, and yet this is several times the amount used even in long distance instruments.

It may be of interest to note that in one of Dr. Wietlisbach's experiments the secondary current from a Blake transmitter over a resistance of 1,000 ohms was .0000547 ampere. Prof. Cross, with a resistance of 400 ohms and 512 vibrations per second, obtained from three different instruments, using Blake, Edison and Hunning's transmitters, currents ranging from .000072 to .000556 ampere, the windings of the coils not being given. The small amount of current used shows the extreme sensitiveness of the telephone receiver.

A PRIMARY LESSON.

Most of our readers understand something about this subject of induction coils, and yet there are some well-informed telephone men who review it occasionally. The best training in telephone work is a course of study in alternating currents, as applied to power and lighting, because these currents being

larger and the alternations (reversals) less rapid, their effects and peculiarities can be studied more closely, and a great many things which puzzle the man who knows nothing but telephone work, become plain to the one who has studied the former.¹

While the induction coil may be constructed in a variety of ways and possess any shape or size which will give the correct transformation, the most common form employed in telephone work is the one shown in Fig. 49, in which the primary is

FIG. 49.

wound in a comparatively small number of turns around the iron core, and the secondary, with a larger number, wound outside. In order that the battery pressure may be increased when connected to the primary, it is necessary that the secondary winding should have a great many more turns, and in order to bring it as near to the iron core as possible the wire is a great deal smaller, usually about No. 36 or No. 40, and, of course, its resistance is much higher. Now this resistance is not a virtue, for we would prefer to do without it if we could. In order that the sound waves may not be distorted too much, the coil and iron core must not exceed a certain size, say 4 inches in length, and as the primary coil is wound on the spool with from 100 to 200 turns, and the secondary from 3,000 to 5,000 turns, it is easy to see that it must be very small to keep it within the space allotted to it. The proportions are a matter of considerable importance and in order to obtain good service they should all be as nearly alike as possible, as coils of the same size, windings and resistance will help each other out.

According to experiments made by W. H. Preece, the most successful coil for all-around work up to 50 miles, was a coil with a resistance of .5 ohm in the primary and 250 ohms in the secondary, and the best coils yet found for local business, at least in connection with the Blake transmitter, have about this proportion.

On measuring up about a dozen instruments recently, some of the latest the Bell Co. have sent out of the Blake pattern, I found the resistance of the primary coil measured through the switch to average .8 ohm (though one was found as low as .27 ohm), with the secondary coil measuring from 250 to 260 ohms,

FIGS. 50 AND 51.

and the Blake transmitter button, with a rather loose adjustment, varying from 2.29 to 4.4 ohms. These instruments were as satisfactory a lot of Blake instruments as the Bell Co. ever turned out, which led me to think they had struck about the right proportion. With the long distance, solid back instruments, however, the case was different, the resistance of the transmitter being from 12 to 30 ohms, which required, of

¹Those who wish to follow this subject further may refer to the following books: The Alternate Current Transformer in Theory and Practice, Vol. I, by A. J. Fleming; Handbook on the Telephone, by Preece and Stubbs, and Theory of Telephonic Transmission, by Dr. V. Wietlisbach.

course, two powerful Fuller cells and a larger coil, it measuring $4\frac{1}{2}$ inches long, the primary winding measuring 1.5 to 2 ohms and the secondary from 18 to 19 ohms.

Of course it must be remembered that a loose carbon contact is quite an uncertain factor, but still it comes near enough for comparisons to be made, and some of the most successful independent instruments showed similar results.

One American Electric solid back transmitter showed good results with a coil about $4\frac{1}{2}$ inches long with secondary resistance of 220 ohms, while another good talker, an old style Kokomo Hunning, has a secondary of 230 ohms (long coil), and a primary circuit of 15 ohms, including the transmitter.

This high resistance of the Hunning, or any granulated carbon transmitter, makes two or more cells of battery necessary in order to give the proper magnetizing force to the primary coil. But too many turns means sluggish action in the coil, and therefore the winding in the primary should not exceed 1.5 ohms, with say a winding of perhaps 225 ohms in the secondary; but whatever coil is adopted, take that as standard, and make other coils conform to it.

If a coil is too small, we have clear articulation, but very weak sounds. If the coil is too large, we have loudness at the expense of clearness, and sound waves are so complicated in character that it is a constant source of wonder to the electrical engineer that they are transmitted at all. In currents used for lighting and power, it is the aim of the dynamo builder to so balance his coils that the resultant waves will come in the form of a sine curve (Fig. 50) in which the current starts at zero, rises to a maximum at B, falling to zero again at C, then repeating the performance in the opposite direction. Such a curve can be transmitted further with less loss, than any other; and the more a wave departs from this form the greater the distortion from resistance, self-induction, retardation, etc. An example of this can be seen in the way cable messages are received across the ocean. In crossing the ocean the dots and dashes, made on the siphon recorder, encounter so much wave distortion that they could not be distinguished, except by an operator used to these peculiarities, the difficulty increasing with the speed; for the higher the speed the greater the wave distortion. But the highest cable speed hardly means more than from 10 to 20 impulses per second, while a telephone has to take from 200 to 2,000 per second, and besides the telephone wave is not a sine curve as shown in Fig. 50, nor a series of distinct impulses as in a cable message, for if it were telephonic transmission would be an easier problem. Besides it is pretty well known that pure musical tones can be transmitted much further than articulate speech, because musical tones more nearly represent a sine curve. Articulate speech is so loaded down with overtones that the curve looks more like that shown in Fig. 51, and yet in spite of all this, every one of these is reproduced if the line is not too long.

The Evolution of the Telephone Line Signal.¹

BY ARTHUR VAUGHN ABBOTT.

A CAREFUL observer at the first great American Exposition, the Philadelphia Centennial, might have noticed a fine wire running along a gallery in Machinery Hall, terminating at either end of the building in a small closet. Continued investigation would have disclosed a curious trumpet shaped apparatus into which the wire extended, whereby an attentive listener could, with the aid of a vivid imagination, distinguish articulated sentences delivered at the other extremity of the wire. Such was the first public exhibition of the telephone, whereby the transmission of speech by electricity became a fact, and in the quarter of a century which has since elapsed, electrical arachnids have been so industriously spinning a copper web that upwards of 600,000 miles of telephone wire now cover this continent, placing some 400,000 persons in talking relations with each other, and annually transmitting about 900,000,000 messages. But the invention of the telephone was only half the solution of the transmission problem, for the instrument itself was useless without the necessary connecting circuit. Receivers and transmitters are now much the same that they were twenty years ago, but a vast amount of skill and ingenuity has been expended upon apparatus for rapidly, effectually and economically placing subscribers in talking relations with each

other, and the telephonist of to-day is essentially a "Transmission Engineer."

When telephonic communication is limited to two persons, it is simplicity itself to connect them by the requisite circuit and provide proper signals to attract attention to the reception of messages, but when the number of correspondents in a single locality is to be numbered by thousands and tens of thousands, it is physically and financially impossible to erect a line from each station to all of the others, so early telephone undertakings developed the idea of the "central office," to which lines from all subscribers in the immediate vicinity converge, equipped with the necessary paraphernalia for interconnecting at pleasure any pair of circuits. To carry out the exchange system, the first requisite is to provide each circuit with some form of apparatus whereby the person desiring to send a message may gain the attention of the central office attendant. As the early telephonists comprised many recruits from the "locksmith and bell-hanger school," to which the degree of "electrician" had recently been added, on account of a supposed familiarity with the installation of electric bells, it is not surprising that the earliest line signal was the then crude form of hotel annunciator. It consisted of a pair of bulky spools wound with cotton covered wire, over which an armature was pivoted, carrying a catch that normally retained in a vertical position a door, or shutter. Electrical excitement of the spools released the catch and allowed the shutter to fall forward, disclosing a name or number painted upon its inner surface. From the falling shutter, this piece of apparatus obtained the euphonious name of "drop," and as originally designed it was exceedingly clumsy, occupying a space of 2 inches by $3\frac{1}{4}$ inches, so but a very slight exhibition of mechanical skill sufficed to refine and compact it to a notable degree. When it was attempted, however, to set annunciators of this improved description in sufficient proximity to each other to place before a single operator such a number of lines as it was possible for one person to adequately serve, much difficulty was experienced, due to the cross-talk developed by magnetic leakage between the spools of adjacent signals.

Increased mechanical skill and electrical knowledge obviated the cross-talk difficulty by ironcladding, and in this form, known as the "tubular drop," the line signal remained in statu quo for a number of years, and is still very widely employed. But in spite of improved mechanical and electrical details the tubular drop proved itself to be anything but an efficient signal. The falling shutter frequently did not attract the notice of the operator, even though the latter were careful and attentive. Accumulation of dust, either around the trunnions supporting the armature, or under the shutter hook, prevented the shutter from falling, and if adjusted for maximum sensitiveness, the slightest earth current, or the discharge from a summer thunder shower was often sufficient to display the signals of an entire switch-board. It is necessary to manually restore the shutter every time it falls, thus necessitating a considerable expenditure of time and energy for this purpose, and so the next step was the so-called self-restoring drop.

Here great skill has been displayed in mechanically designing and constructing the signal. The head of the drop is provided with a double shutter, one thick and heavy of iron, retained in its place by a lever catch connected to the rear armature; the other, a thin outer flap of aluminum that normally conceals the number painted upon the iron disk. Electrically, there are two spools. The right hand winding is designed for the calling circuit, and when excited attracts the rear armature of the drop, lifting the catch and allowing the heavy iron shutter to fall forward, thus raising the aluminum flap and disclosing the number. The other winding comprises the restoring circuit, consisting of a smaller spool which may be excited by a battery controlled by the operator in front of whom the drop is placed, the magnetism thus developed being sufficient to pull the heavy iron shutter back into its place, allowing the aluminum flap and catch to return, thus restoring the drop to its calling position. Line signals should possess five characteristics: 1. Certainty in operation. 2. Ability to immediately attract attention. 3. Positiveness in the information conveyed. 4. Compactness. 5. Automatic operation.

The attempt to simultaneously attain all of these features has given rise to hosts of devices which, for purposes of classification, may be roughly divided into three groups: 1. Electric signals. 2. Electro-mechanical signals. 3. Luminous signals.

The self-restoring drop is the best illustration of a signal of

¹Presented at the fifteenth general meeting of the American Institute of Electrical Engineers, Omaha, June 29, 1898. Abstract.

the first class. The excitation of the tripping coil by the subscribers' ringing current exhibits the signal, while with the second circuit the operator electrically restores the signal to its normal position. A particularly successful one, reliable, compact and automatic, consists of a spool surrounded by a pivoted sheet iron armature. Normally, the armature is out of sight, but on exciting the spool the magnetization induced causes the armature to rise, displaying the number painted upon the face of the armature. From the method of operation, this signal has received the suggestive cognomen of "tip-up." Unfortunately this signal is only well adapted for use where battery currents are employed, as it is not so effective with alternating currents, and in order for the signal to remain visible the magnet must be continuously excited. In another arrangement, which is ingenious and seems to possess much merit, but has never received a wide application, the usual exciting spool is supplied with a pair of projecting pole-pieces which surround a slightly inclined tube. In this tube a silvered steel ball is placed and the tube so inclined that normally the ball rolls out of view. When the spool is excited the magnetization developed causes the ball to roll forward and to project through a plate covering the orifice of the tube, which also prevents it from being expelled and lost.

Many forms of luminous signals have been suggested, but the only one in successful operation at present is the miniature incandescent lamp which has, on the whole, proven itself of the greatest value. So far as the writer can ascertain, the idea of employing incandescent lamps for signal purposes arose with Mr. J. J. O'Connell, of the Chicago Telephone Company, who suggested in 1888 the employment of an incandescent lamp upon burglar alarm circuits in order to permit the legitimate occupant of a protected room to send to the alarm office an identification signal whereby his entrance to the premises could be made known.

In the latter part of the summer of 1890 some of the trunk lines in use in Chicago were provided with disconnect signals using miniature incandescent lamps. At the receiving office the trunk lines terminated in the ordinary cords and plugs used upon a telephone switchboard, in front of each of which an incandescent lamp was located. So long as the line was in use a relay in conjunction therewith was excited by battery current flowing over the line, and its armature drawn up. As soon as conversation was completed the operator at the originating office withdrew the plug from the trunk line jack at that office, thus opening the battery circuit and causing the relay to be de-energized; the release of the relay armature completed a local battery circuit, illuminating the incandescent lamp. The operator at the receiving office, noticing the illumination of the lamp, was thereby informed that conversation was completed and instructed to remove the trunk line plug. As the local lamp circuit was carried through the operator's listening key, the placing of this key in the testing position extinguished the lamp. A very short experience served to demonstrate the superiority of incandescent lamps over any other form of signal, for the illuminated lamp was at once so positive and distinct as to instantly attract the attention of the operator, thus markedly accelerating switchboard work. As a result of this experience, most of the trunk lines in the main office of the Chicago Telephone Company were rapidly supplied with lamp signals.

In the spring of 1893 it was proposed to re-equip a large multiple board in the Chicago exchange with self-restoring drops, but the expense and difficulty of this change caused the management to hesitate, and at this time the writer suggested the employment of incandescent lamps as subscribers' line signals on the ground of greater economy in space, and in installation, as well as improved signal efficiency. More conservative telephonists doubted the wisdom of such a recommendation, fearing that the numerous relay contacts would be a perpetual source of trouble, and no further steps were taken with this project. In the winter of 1894 a new type of switchboard known as the "express board" was introduced. As this board was designed to meet the wants of metallic circuit subscribers, particularly those whose telephonic business was large, it was decided to provide incandescent lamp line signals. The circuit of this board was so arranged that on the removal of the subscriber's receiver from its suspending hook, the movement of the hook closed the circuit and allowed battery current to flow through the line. This current actuated a relay at the exchange, in the local of which the signal was placed, situated behind a ground glass shade upon which the number of the subscriber was painted. The

illumination of this disk displayed a very distinct and conspicuous signal that immediately attracted the operator's attention. Notwithstanding some apprehension as to the possibility of trouble with relay contacts, the service given by the lamp signal was, on the whole, so satisfactory as immediately to concentrate telephonic attention upon the use of lamps, and within the four years that have since elapsed, the superiority of the incandescent lamp for this purpose has been so fully demonstrated that nearly all of the large switchboards which are at present being constructed are completely supplied with signals of this description.

As the service to which the incandescent lamp when used as a signal is subjected is peculiar, the employment of lamps upon telephone switchboards has afforded lamp manufacturers a new problem. In the early experiments ordinary miniature lamps of low voltage were employed. As these lamps were bulky and consumed a large amount of current, the first attempts at improvement were directed to obtaining a smaller and more economical lamp. The early lamps were designed entirely to fit a socket with a screw thread. The socket consisted of a brass tube, in the bottom of which a screw base was placed matching the thread upon the lamp. A cap carrying a ground glass shade covered the front end of the tube, while from the rear two conductors extended, one fastened to the thread of the socket, thus connecting with one of the lamp leading-in wires, while the other was arranged to make contact with the other leading-in wire in the centre of the lamp base. This conductor was supplied with a spiral spring, the pressure of which it was expected would lock the lamp in its place and constantly maintain good electrical contact. This expectation was not fulfilled, for one of the greatest troubles encountered has been the loosening of the lamp in its socket, due to the almost inappreciable jarring to which all buildings are subjected. Lamps in sockets of this description will gradually unscrew, opening the electrical circuit; they are then incapacitated as signals and considerable complaint will arise. Lamp sockets of this kind could be placed on wooden strips for mounting in the switchboard on one-inch centres. The present lamp occupies no greater volume than that required by a spring-jack and may be inserted into sockets composed of pairs of springs arranged on a rubber strip. Such sockets so closely resemble standard spring-jacks that they are called "lamp-jacks," for they occupy the same space, and may be secured in the switchboard in the same manner. By placing alternate strips of lamp sockets and jacks, the subscriber's line signal and answering jack may be more closely associated than has previously been possible, space economized in the switchboard and service accelerated.

The Szczepanik Teleelectroscope.

EVER since the announcement of the invention of the teleelectroscope, an apparatus for the transmission of scenes and pictures over a wire, by the young Polish school teacher, Szczepanik, vague and exaggerated reports have been circulated in the daily press. Now, however, the details of the invention have been obtained by the New York "Herald," from which the following interesting account and diagrams are taken:

In Fig. 1 A represents the apparatus of the transmitting and A' that of the receiving station. The transmitter resembles the telephone box. Usually a telephone is connected with the teleelectroscope to make conversation possible simultaneously with the sight of the object. In the teleelectroscope the beams of light composing the picture are concentrated by means of a lens at G similar to the concentration of the sound in the mouthpiece of the telephone. The subdivision of the picture into single points is effected by two small reflectors, of which one is a (figure 1 A) and the other a d.

The reflector a is mounted upon a sheet of iron, the reflector being at a right angle of the diagram. By this reflector a (Fig. 1 and Fig. 2) a very small stripe of the picture G is reflected and in vibrating up and down the whole picture G will be reproduced stripe after stripe. The reflector's vibrations are effected by means of an electromagnet E, mounted below it, in a similar manner to the vibration of the membrane in a receiving telephone. At a right angle to this first reflector is a second reflector a d. The reflections cross one another in only a single point, and, therefore, the reflectors suitably vibrated, the whole picture must reappear in the reflector a d in form of consecutive points of light.

Figs. 3, 4, 5 and 6 illustrate the movement of those two reflectors in consideration. Let x be the direction of reflector a and y the direction of the reflector a' . Suppose both lines to be moving exactly in the same time over the same distance x and y , so line K must appear as the result of these movements as reflected picture at the point O (in Fig. 1) in the form of points following one another; in case the vibrations of the reflectors be always the same, the line K would be always repeated at O . If there be a greater difference in the vibrations of the reflectors the line K will look like Fig. 3 and Figs. 4 and 5.

In case the differences in the vibrations be small, Fig. 6 represents the line K .

FIGS. 1, 2 AND 3.

represents the line K . As will be seen by those figures, it will be possible by suitably regulating the vibrations of the two reflectors to subdivide and reflect the whole picture in the direction of O , Fig. 1. Suppose every reflector would make a hundred vibrations in a second, then 100 times 100 different points of light would result. But it is possible to bring up each reflector to several thousands of vibrations, and consequently the number of points will run up into the hundred thousands and millions.

These points of light fall upon a plate of selenium, S . On this plate are mounted several selenium cells, because a single cell would not answer quickly enough to the necessary alternations. A clockwork keeps the plate in a constant rotation, offering to the light arriving in O always fresh cells. It may be mentioned that the point of light by suitable means must be enlarged so as to cover the whole selenium cell. At S an electrical current en-

FIGS. 4, 5 AND 6.

ters the selenium ring, leaving it near by, and, owing to the peculiar actions of light upon selenium, a larger or smaller amount of current is allowed to pass.

The vibrations of the current thus produced arrive through the wires L at Fig. 1 A^1 the receiving station. Here at O^2 is a natural (daylight) or artificial (electric) source of light, the beams of which can enter into the apparatus through a very fine slot of variable width. The vibration of the electrical current effects also the enlarging or the reducing of the slot. Technical details of this part are not available, and there is much guesswork as to its nature. To understand the nature of the apparatus one has only to bear in mind that the brighter the point of light acting upon the selenium cell in the receiving apparatus the

more current will be let through, and thus so much more the slot at O^2 will be opened. More light will enter, which will fall upon P^1 , and from there upon the vibrating reflectors a' and a and from there to the ground glass G^1 . The dark points of G allow less light to act upon the selenium cell at O (Fig. 1), less current will pass, less light will enter at O^2 , and a dark point will appear at G^1 .

To get a picture, as already stated, the motion of both systems of reflectors has to be synchronical; that is to say, the reflector a must swing as quick as a' , and reflector a as quick as a' , a condition which is met by telephones giving the same tone.

According to the testimony of eye-witnesses the transmission of pictures is perfect, and the central committee of the Paris Exposition of 1900, where the invention will be shown for the first time to the public, have guaranteed the young inventor 3,000,000 francs. At least, "that's what they say." We are not aware of the existence of a Central Committee of the Paris Exposition.

Second Annual Convention of the Independent Telephone Association, Chicago, June 30, July 1 and 2.

THE Independent Telephone Association of the United States met in its second annual convention at the Palmer House, Thursday, June 30, 4 o'clock p. m., and continued in session during Thursday evening, Friday, Friday evening and Saturday morning. The attendance was excellent, representatives from independent exchanges and toll lines being present from fourteen States. The interest manifested was great, and reports from all sections of the country showed a very vigorous growth and extension of the independent telephone movement throughout the United States. The programme as announced was carried out.

A committee consisting of H. D. Critchfield, of Ohio; S. P. Scherin, of Indiana, and H. K. Cole, of Kentucky, was appointed to propose changes in the constitution as adopted at Detroit in June, 1897. This committee submitted the following report, which, after full discussion, was unanimously adopted:

Your committee to which was referred the proposed changes to the constitution of the Independent Telephone Association of the United States beg leave to submit the following report:

We recommend first, that section 2 of article 3 be amended so as to read as follows:

"Section 2. The payment from time to time of such further assessments as the association, through its proper committee, may levy, not to exceed in any one year ten cents for each telephone in use by any exchange or toll line company, and ten cents per mile of toll lines carrying a wire or wires over which paid messages are transmitted."

We further recommend that section 3 of article 3 be amended so as to read as follows:

"Section 3. Any corporation, partnership or individual engaged in the manufacture of telephones and switchboards, or either, may become a member of this association upon payment of a membership fee of \$10 and annual dues in the sum of \$100. The membership fee to be paid but once, and the annual dues for the first year to accompany said membership fee, and be paid annually thereafter upon notification by the secretary of the association."

"Any corporation, partnership or individual engaged in the sale of apparatus or materials used in the construction, operation or maintenance of an independent telephone exchange, toll line or system, except such corporation, partnership or individual as may be engaged in the manufacture and sale of switchboards and telephones, or either, may become a member of this association upon payment of a membership fee of \$10 and annual dues in the sum of \$50, to be paid in like manner and time as hereinbefore provided for the payment of the same by manufacturers of telephones and switchboards."

Your committee further recommends that article 4 be amended so as to read as follows:

"Section 4. The officers of this association shall be a president, three vice-presidents, a secretary, two assistant secretaries, a treasurer and an advisory board consisting of nine members, two of whom shall be the president and secretary of this association, together with seven members, who shall be selected by the executive committee. The president and secretary of the association shall be ex-officio chairman and secretary of the

advisory board and executive committee, respectively, provided, however, that no person representing either himself or any firm or corporation admitted to membership under the provisions of section 3 of article 3 of this constitution, may be elected to or hold an office therein."

Your committee further recommend that article 3 be amended so as to read as follows:

"Article 8. Each member of this association shall be entitled to one vote for each 500 telephones or less, or for each 500 miles of toll lines or less, in actual use, and one additional vote for a major fraction of 500 telephones or miles of toll line in actual use, and no more, on the election of officers, or as to any question which may be voted upon by said association, provided, however, that each person, firm or corporation admitted to membership under section 3 of article 3 of said constitution shall be entitled to one vote."

Your committee further recommend that article 4 be amended so as to read as follows:

"The officers of this association shall be a president, three vice-presidents, a secretary and treasurer in one person, two assistant secretaries, and an advisory board, consisting of five members, two of whom shall be the president and secretary of this association, together with three others who shall be selected by the executive committee. The president and secretary of the association shall be ex-officio chairman and secretary of the advisory board and executive committee, provided, however, that no person financially interested in the manufacture or sale of telephones or supplies or materials used in the construction, operation or maintenance of a telephone exchange or toll lines shall be eligible as an officer or member of the executive committee of said association."

Your committee further recommend that article 5 of the constitution be amended so as to read as follows:

"The association shall elect an executive committee, which shall consist of one member from each State, each State through its delegates to suggest the name of the member of said committee to represent such State. Should any State be without representation in the convention the convention shall then select one member from such State, who shall act until the vacancy shall be properly filled under this article. The executive committee shall, with the consent of the advisory board, select such sub-committees, as it deems expedient and necessary, and shall fully empower such sub-committees to carry out the object for which they were created."

Your committee further recommend that section 3 of article 7 be amended so as to read as follows:

"The secretary and treasurer shall keep the minutes of the association. He shall collect all moneys and receipt for the same. He shall pay all properly executed orders and drafts provided for in this constitution, and all other orders signed by the president under the direction of the advisory board. He shall keep an accurate account of all receipts and disbursements of money, and make a report thereof at each annual meeting of the association, and to the executive committee and advisory board whenever called upon so to do. He shall issue and mail all official calls and perform all other duties required of him by the association. He shall receive such salary, not to exceed four hundred (400) dollars per year, as may be fixed by the executive committee, and shall have an allowance for expenses to be paid upon the approval of the advisory board on presentation of properly executed vouchers. His salary shall be paid at the end of each quarter by draft upon the treasurer. He shall give bond in such sum as the executive committee may require, with security to be approved by the advisory board."

Your committee further recommend that section 5 or article 7 be stricken out, and that the offices of secretary and treasurer shall be vested in one person.

Your committee further recommend that section 1 of article 7 be amended by striking out the words and figures "\$2,500 per year," and inserting the words and figures "\$1,200 per year," thereby reducing the salary of the president of the association from \$2,500 to \$1,200 per year.

Your committee further recommend that article 14 be amended so as to read as follows:

"The election of officers shall be by ballot whenever two or more names are presented for the same office, and shall be conducted by three judges and two clerks, to be selected by the presiding officer. The presiding judge shall announce the name of the voter before the ballot is deposited in the ballot box, and

should any member challenge the vote the judges shall then proceed to hear the objection and shall determine the rights of the voter. No vote shall be cast upon the election of officers or any other question which may be voted upon at any meeting of said association except by a member thereof present in person."

These changes met with unanimous approval of the members present.

After the adoption of the report of the Revisional Committee the association proceeded to the election of officers, and the following were elected for the ensuing year:

President, James M. Thomas, Chillicothe, O.; first vice-president, H. C. Young, Columbia, Pa.; second vice-president, S. T. Slade, Oskaloosa, Ia.; third vice-president, J. B. Weare, Grand Rapids, Mich.; secretary and treasurer, W. J. Vesey, Ft. Wayne, Ind.; first assistant secretary, George W. Beers, Ft. Wayne, Ind.; second assistant secretary, D. C. Dow, Cobleskill, N. Y.; advisory board, James M. Thomas, Chillicothe, O.; W. J. Vesey, Ft. Wayne, Ind.; H. B. Critchfield, Mt. Vernon, O.; Hugh Dougherty, Bluffton, Ind.; E. B. Fisher, Grand Rapids, Mich.

After the election of officers and their assuming their respective duties, the following resolution was offered:

Whereas, The express companies have in many cities all over the country, presumably at the instigation of the Bell telephone monopoly issued orders directing the taking from their several offices such telephones as are not furnished free of charge,

And Whereas, We regard this act as a direct assault upon the independent telephone interests of the whole country,

Therefore, be it resolved, That the Independent Telephone Association of the United States in annual convention assembled, believing that just compensation for service and a right to enter into a fair competition in every line of business is the inalienable right of American citizens, do denounce this action of the express companies as an outrage upon the common rights of citizenship, which we advise and urge all the local independent companies to resent each in its own way, appealing to their patrons and fellow-citizens to aid them in their efforts by sending as many of their light shipments by mail or fast freight as possible, and we especially recommend that all independent telephone companies order all their own exchange and line supplies shipped in like manner.

This resolution, after full discussion and careful consideration, was adopted without dissenting vote.

After transacting miscellaneous business and general discussion, the association adjourned to meet in June, 1899, at a time and place to be hereafter fixed by the executive committee, unless sooner called in convention by the president.

Mr. Joseph Donohue, Western manager of the American Electrical Works, was on hand during the convention distributing packs of playing cards among the members and incidentally mentioning the merits of his wire. Mr. W. T. Blaine, the president and general manager of the Victor Telephone Manufacturing Company, was busy making many new friends among the delegates, as was also his electrician, Mr. E. E. Yaxley.

No electrical convention of any description would be complete without the presence of the genial W. W. Lowe, the popular president of the Electrical Appliance Company. Mr. Lowe came early and stayed late. Mr. Barron, representing the National Carbon Company, was an interested visitor. The interests of the Western Telephone Construction Company were well taken care of by Mr. Cooke, Harry C. Dodge and Mr. Platt. They made their headquarters in the lower floor in the north end of the hotel. Mr. James E. Keelyn, president of the Western Telephone Construction Company, did not put in an appearance until the second day, when he was warmly greeted by his old associates and friends. Mr. W. E. Doolittle was in attendance all three days, assisting the delegates in their trips to the new switchboard factory on West Quincy street, Chicago. Mr. Young, of the Columbia Telephone Company, circulated among his friends and presented his card as candidate for treasurer of the association. Mr. P. C. Burns, of the American Electric Company, added his six feet two inches to the throng and induced many of the delegates to visit his large factory on South Clinton street. James S. Healey, representing the Julius Andrae & Sons Company, Milwaukee, was also in attendance. The interests of the Stromberg-Carlson Telephone Company were in the hands of Mr. A. Stromberg and Mr. Henry Shafer.

The genial and portly James W. Brennan was present every day. Mr. Brennan is an old telephone man and knows everybody in the trade.

The electrical press was represented by Messrs. Kammeyer, Woodbridge, Church, Piny, O'Hara and W. J. McConnell.

Omaha Meeting of the Electrical Engineers.

THE American Institute of Electrical Engineers convened their 15th general meeting in the Trans-Mississippi Exposition City on June 27. Daily sessions were held in Royal Arcanum Hall, in the Bee Building, and were of special interest to all who attended during the four days' meeting.

The Institute met promptly at 9:30 o'clock Monday morning, and was called to order by Dr. A. E. Kennelly, of Philadelphia, president, who delivered the inaugural address, which was an excellent reviewing of the growth of electrical science in the decade and a half from 1884, the date of the birth of the Institute. He referred to the marvellous progress that has been made in all branches, in a financial, scientific and experimental way. His address was very exhaustive and sketched the great strides made in telegraphy, telephony, electric railroads, lighting and the less popular branches, down to the Roentgen rays and the wireless telegraphy, which is now passing through the experimental stage and will enter practical service in the future.

President Bingham, of the Omaha City Council, in a neat address welcomed the guests to the city, and was followed by President Wattles, of the Exposition, who pointed out the stupendous project they would witness and spoke at length upon the electrical features of the show.

Manager Edward Rosewater, of the Department of Publicity and Promotion of the Exposition, was introduced, and spoke of the aims and objects of the Institute. He related a number of anecdotes of the condition of telegraphy during the Civil War, when he was employed as chief telegraph operator at General Rosencran's headquarters a part of the time. Mr. Rosewater said that upon a certain occasion he had written to Prof. Bell, asking him for a list of books upon electricity, and was answered to the effect that there were no published authorities, and was advised to confine his studies to his own observation of electrical phenomena.

A royal welcome was also extended by Col. J. J. Dickey, Superintendent of the Western Union Telegraph Company, who greeted the visitors not only as a man engaged in the profession and a resident of Omaha, but also as a member of the Court of Ak-Sar-Ben. An invitation from King Sampson to attend the festivities in the den the same evening was also presented by H. J. Penfold, of the Board of Directors, later in the session and accepted.

The regular business was then introduced by the reading of the following papers: "The Dielectric Strength of Air," by C. P. Steinmetz, of Schenectady; "Two Wire Distributing Systems and Lamps of 220-240 Volts," by John W. Howell, of Newark, N. J.; "A Capillary Electrometer for Electrical Measurements," by Charles F. Burgess, of Madison, Wis. Mr. Howell was not present and his paper was read by Secretary Pope. After the reading of the papers the authors were called upon to answer many questions and take part in the general discussion which continued for a couple of hours.

In the afternoon the local committee of entertainment in charge of the guests visited the Grant Smelting Works and the Union Pacific shops, and at night were initiated as members of the Knights of Ak-Sar-Ben, where fun fast and furious raged for several hours.

Tuesday morning's session opened with the reading and discussion of George A. Damon's paper on "A Modern Electric Central Station." The paper proved to be a very interesting description of the modern plant of the Imperial Electric, Heat and Power Company at St. Louis, which Mr. Damon cited as a good example of the present tendency in electric power station practice. A discussion followed at some length on several other important papers, after which the Committee on Standardization, comprising Francis B. Crocker, chairman; A. E. Kennelly, C.

T. Hutchinson, J. W. Lieb, Charles P. Steinmetz, Lewis B. Stillwell and Elihu Thomson, presented their preliminary report. The object, as set forth in the report, is the consideration of necessary changes in order to secure uniformity and of what kind and size the apparatus in electric supplies should be. The report, which is not yet to be made public, was gone over section by section and discussed in a brisk interchange of ideas on phases of the matter. It was conceded that it would be desirable if a more generally approved system of standards was adopted.

The afternoon was given up to sightseeing at South Omaha. In the evening the party met at the Machinery and Electricity Building, where a special electrical display had been arranged by the General Electric Company, which was much admired. Afterwards the party, escorted by Luther Stieringer and Henry Rustin, of the Exposition, traversed the Grand Court, and for an hour or more enjoyed with highest delight the wondrous beauties of the grand illumination which it presents.

Later the Press Building was visited, where an invitation was extended to the guests by Mr. Stephen von Szinneyey, formerly of the Press Club, New York, now managing the famous German village (Deutsches Dorf) at the Exposition to visit the place, which was accepted unanimously, not a single dissenting vote being announced. Through the personal efforts of Mr. Luther Stieringer arrangements were made with Gaston Akoun, of the "Streets of All Nations," and Henry Roltair, of "The Explosion of the Maine," for special performances, which were given at both places in honor of the distinguished guests.

Wednesday morning was devoted first to the reading of a paper by Ernst J. Berg, of Schenectady, on "Transmission and Distribution of Power for Railway Service." The paper was discussed at considerable length, and many valuable points relative to power and its general distribution were brought out.

Albert H. Armstrong read a paper on "Some Phases of the Rapid Transit Problem," and added to it a number of diagrams which he used as illustrations. This paper was of special interest to street car people, as it dwelt almost exclusively upon street car service. It discussed the points of power, fuel, cost and various phases of moving cars and people, the point being how to move the most people in the shortest time at the least cost.

A lengthy discussion followed the reading of the paper, which was participated in by Dr. Eddy, Mr. Arnold, Professor Goldsborough, Messrs. Steinmetz and Pope.

D. C. Jackson, Madison, Wis., not being present, his paper on "The Commutated Curve of a Composite Wound Alternator," was read by title. Other papers were referred.

The remainder of the day engaged the members in business and social intercourse, and at night, by invitation of the Omaha Street Railway Company, a trolley ride was accepted to visit Fairmount Park, Council Bluffs, Iowa, to which pleasure resort a ride of seven miles in a special car was enjoyed by the visitors and refreshments were supplied by the Committee on Entertainment in a generous manner.

The session on Thursday morning was opened by the reading of a paper on "The Graphic Treatment of Alternating Currents in Branch Circuits," by Dr. Eddy, of the State University, St. Paul, Minn., which was afterwards discussed at length in an interesting manner.

Prof. W. E. Goldsborough read a paper on "Air Core Distribution," which he illustrated with charts, and many valuable points were explained in a highly acceptable manner.

The paper of the day was then read by Charles F. Scott on "High Voltage Power Transmission."

Mr. White, Chairman of the Committee on Entertainment, introduced a resolution extending a vote of thanks to the Exposition Management, the Union Pacific Railway system, the Omaha Electric Street Railway Company, the daily press and to all others who had so kindly added in making the occasion one of genuine pleasure to the members of the Institute.

Mr. Steinmetz amended the resolution thanking the citizens of Omaha for their hospitality, which was adopted, as also the resolutions offered by Mr. White, of the Committee.

Mr. Pope spoke in terms of the highest praise of the papers read by the Western members, some of whom had not been heard at previous meetings. He went on to say that, although the attendance at the present meeting was not as large as at former ones, quality and not quantity should be considered, and in this respect the meeting had been the most enjoyable and successful ever held in the history of the Institute.

He congratulated the members on the creditable work done during the past year and also called attention to the telegraphers who had taken part in promoting the success of the meeting.

Dr. Kennelly closed in a very appropriate manner.

On motion of Mr. Steinmetz a vote of thanks was tendered to Prof. Owens, Superintendent of the Bureau of Machinery and Electricity at the Exposition. The latter made a short response, saying that it was a great pleasure to him to have assisted in entertaining the Institute.

The report of the committee to consider the plan of organizing the experimental resources of the various electrical laboratories in the United States was read by Chairman Owens. This report is only preliminary, and recommends the Council to take this matter in charge. The report was adopted.

The plan is to send circular letters from the committee to persons in charge of the laboratories requesting them to join in the movement and explaining the object in full.

Among those of the Committee on Arrangements instrumental in promoting the pleasure of the visitors and in doing all in his power to have them remember the Omaha meeting for years to come was Mr. Edward F. Schurig, City Electrician of Omaha, whose polite attention and kindly consideration of the needs of the members will serve as one of the pleasant associations to mark the fifteenth mile stone of the American Institute of Electrical Engineers. A pleasant time afterwards spent in songs and toasts and taking farewell ended the meeting held in the Exposition City. The same evening many of the visitors departed homeward, while others prolonged their visit a few days in order to see still more of the enjoyable sights which Omaha this season affords.

NEWS & NOTES

Illumination of the Grand Court at the Omaha Exposition.

BY MABEL BALCOMBE.

NOT only has the grand court of the Exposition at Omaha a fine showing of stately buildings and colonnades, sweeping arches and golden domes, a lagoon, fountain-splashed and spanned by delicate bridges, statues, terraces and tropical plants, but its salient and distinguishing feature is the exquisite blend-

ings—forms the exact curve or straight line best adapted to enhance the surrounding structures. The court is about one-half mile in length and 700 feet across; a lagoon forms the centre, and is surrounded on three sides by seven of the principal buildings, erected in the renaissance and classical styles, and covered with white staff. The place of honor at the west end of the lagoon is occupied by the superb Government building, which resembles St. Peter's in many respects, and may be claimed as superior in design to the corresponding one at Chicago. In front of this structure the lagoon widens out in a

GOVERNMENT BUILDING AND ELECTRIC FOUNTAIN, OMAHA EXPOSITION.

clover-leaf effect, to hold the great cloud-like electric fountain "Nautilus," which plays continually, as shown in the accompanying illustration. A very full illustrated description of this fountain, built from the designs of the well-known electrical expert, Mr. Luther Stieringer, was published in our May 19 issue, with a plan of its pipes and valves. As is evident from the illustration, it is of spray formation and is an embellishment to the scene rather than a separate display.

Looking from the Government building down the north side of the lagoon, the Agricultural, the Manufacturers and the Machinery and Electricity buildings are seen successively; down the south side, the Fine Arts, the Liberal Arts and the Mines and Mining buildings, any one of which, if adequately described, would deserve a separate article. The eastern end of the court is enclosed by a curved colonnade, with the two effective towers

GRAND BASIN, OMAHA EXPOSITION, SHOWING NAUTILUS ELECTRIC FOUNTAIN AND COLUMN OF NEPTUNE.

ing of these elements. The perspective evolved through the artistic arrangement of color proportions and sky lines surpasses in charm all previous expositions. Every building is a lovely unit to an impressive whole; every colonnade—which serves also the practical purpose of a sheltered promenade between the

of an outside building looming up from behind. It is connected in the rear with a viaduct, and is the spot par excellence from which to view the splendors of the grand court by day and by night. Credit for the former is due the architects-in-chief, Messrs. Walker & Kimball, whose instructions to the architects

under them extended even to the proportions, height and style of the different edifices. For the splendid illumination, which is one of the brilliant successes of the enterprise, honor is due Mr. Luther Stieringer, as consulting electrical engineer, from whose designs it was accomplished, and Mr. Henry Rustin, electrical engineer, under whose supervision the entire electrical work of the Exposition has been executed. Although in this instance his entire plan was made before a building was erected, not a light of the many thousands used has been changed. The entire scheme is carried out in 8 and 16 c. p. incandescents. The lower lights outline the bridges, gleam among the shrubbery and surround the fountain Nautilus, like brilliant water lilies floating upon the surface of the pool. On the sprays of white mist and crystal drops searchlight beams in red, green, purple, etc., are cast. Immediately surrounding the lagoon, at frequent intervals, standards about ten feet in height bear clusters of incandescents. Back of these and higher, lines of incandescents bring into relief the pillars of entrances and colonnades, also caps of columns, pedestals and points of vantage. Higher, and receding in the background, roof cornices are encircled, then, above all, domes and spires and towers. On the roof of the Government building flambeaux are raised in standards. Above them, the mammoth dome is outlined in glittering bands; higher up the lights encircle the cupola, then climb to the statue of the Goddess of Liberty and finally blaze from her torch. The perfect diffusion of the light; the carefully studied heights; the absence of arc lights and crude display effects; the art that accentuates instead of overwhelming the beauties of the architecture—all these have produced a most artistic and complete illumination.

Electricity in a Modern Stable.

THE electric motor has become a necessary adjunct to every well-appointed modern stable, whether livery or private, and horses are now groomed and clipped by electricity, with both neatness and dispatch.

The advantages of the application of the electric motor to grooming and clipping machines were early realized by the

FIG. 1.—OLD METHOD OF DRIVE THROUGH DOUBLE COUNTERSHAFTING.

American Shearer Manufacturing Company, of Nashua, N. H., and its effort toward supplying a demand for electrically-driven groomers and clippers has met with considerable success. Hitherto, however, it has supplied merely the machinery, exclusive of the motor, but owing to a demand which has arisen for complete grooming and clipping installations, it is now supplying the motor as well. In doing this, however, it has found it necessary to simplify in a large measure the driving mechanism.

Fig. 1 shows the No. 8 grooming and clipping machine, driven by a bipolar motor through double countershafting with conical

and idle pulleys. This method, while it allows of the operation of two or more groomers and clippers from one motor, was by no means satisfactory on account of the complication of belts and pulleys necessary, and when it became a question of furnishing both driving and operating machinery it was felt that some more direct method of drive was needed. This was found in the small power moderate speed motors developed by the General Electric Company, which, in addition to its line of small power induction motors, has also recently perfected a line of direct current small power motors known as the C. A. type. These motors may be run in any position, either attached to the wall, set on a bracket or hung from the ceiling, and have been found peculiarly adapted to drive the groomers and clippers of the American Shearer Manufacturing Company.

Fig 2 shows the No. 9 machine complete with a 1 h. p. C. A. motor and automatic starting rheostat. In this case no floor space is occupied by the motor and countershafting is eliminat-

FIG. 2.—NEW METHOD OF DIRECT DRIVE WITH C. A. MOTORS.

ed, and the belting is reduced to a single belt from the motor pulley to the pulley attached to the flexible shaft of the groomer and clipper. The motor is fastened to the ceiling beams in an inverted position and the counterpoise, or balance arm, is attached to a swivel on the motor case. The automatic starting box, also fastened to the ceiling, is of the reversing type, with the contact arms pulled in either direction by leather straps. This clipping and grooming outfit is singularly compact and simple and requires almost no attention beyond an occasional oiling. In ordering, it is simply necessary to state the nature and voltage of the current, and, if alternating, the phase and number of alternations.

With the electric motor driven groomer and clipper a horse may be thoroughly brushed in about two and one-half minutes and clipped in about thirty-five minutes.

Holiday Dullness and Strength.

The holidays have interfered with the run of the markets and the course of trade, but conditions are steady and strong, and the glorious news of the glorious Fourth at Santiago has given an upward tendency this week to stocks. It is curious to note the steadiness of prices from the memorable Maine day, February 15, to July 1. General Electric was then 38¼. It has gone down to 29¼ and is now back to 39. Western Union was then 92½. It has been down to 82¼ and on July 1 was 93. Bell Telephone closed the week at 280.

BOSTON, MASS. The Boston Electric Light Company has ordered from Mr. S. M. Hamill, general manager of the Brush Electric Company, 20-160 arc lighters for their new station.

TRADE NOTES AND NOVELTIES

The Bullock Central Valve Engines.

THE illustration on this page shows a triple expansion transfer condensing "central valve" engine of 200 h. p. coupled direct to a street railway generator, running at 380 revolutions per minute, at South Englewood, Chicago, Ill. The engine.

80 h. p. with 160 pounds steam pressure. Even non-condensing engines show a consumption of only 18.7 pounds. The engine is equipped with a very efficient system of automatic lubrication and requires little attendance. The engines are single acting and, there being no reversal of stress on bearings, all parts are always kept in constant thrust. The engines are very compact, therefore occupy small floor space, and are made of the best materials, all parts except the base being built of steel or semi-steel. All parts are interchangeable, and to show how well these engines work under full load, it should be stated that a number of them have been running under full load for periods ranging from 30 to 90 days, without once closing the throttle. Over 200,000 h. p. of these engines are now in use, and, being

TRIPLE EXPANSION TRANSFER CONDESER CENTRAL VALVE ENGINE OF 200 H. P., COUPLED DIRECT TO STREET RAILROAD ELECTRIC GENERATOR, RUNNING AT 380 REVOLUTIONS PER MINUTE, AT SOUTH ENGLEWOOD, CHICAGO, ILL.

which was manufactured by the M. C. Bullock Manufacturing Company, 1170 West Lake street, Chicago, embodies some admirable features which have won for the central valve engine much well-deserved praise. It is very economical in the use of steam, as less than 13 pounds per i. h. p. h. has been recorded under suitable conditions of size and pressure. A consumption of less than 14½ pounds can be guaranteed in engines of only

economical, silent, durable and reliable, they have given entire satisfaction wherever installed.

PROF. W. D. MARKS has been elected president of the new General Electric Automobile Company, recently formed in Philadelphia.

New Rushmore Marine Generating Set and Projector.

FIG. 2.

WHILE the war undoubtedly has a disturbing effect on business, it has created a boom in some lines of electrical work, and manufacturers of marine lighting equipments have been reaping a harvest. Among the more fortunate ones are the Rushmore Dynamo Works, of Jersey City, N. J., who, at the beginning of war, realized that there would be a great demand for their goods and at once commenced working to their utmost capacity. They were thus able to meet all the demands of the Government for the equipment of the large fleet of auxiliary and transport vessels, and in the past sixty days they have shipped over 100 complete searchlight equipments.

We illustrate herewith some of the latest type apparatus built by this company, who have for years made a specialty of marine equipments. Fig. 1 shows their latest type marine generating set with multi-voltage dynamo rated at 15 k. w.

at 500 revolutions per minute. The engine is built after the latest torpedo boat practice, all parts are of finished forged steel, and the governor is of the improved Rites pattern and controls the speed within one-quarter of 1 per cent. In the cut, the

FIG. 1.

splash guards are removed to show the working parts. The dynamo operates on the Rushmore multi-voltage system. It has a simple parallel armature, and will deliver its entire output to a single circuit at one voltage or at as many different voltages and to as many entirely separate circuits as there are pairs of poles.

In marine plants with storage batteries the machine runs in

parallel with the battery at full load, and at light load one pair of brushes is connected at the switchboard to the lighting circuit and the other pair is connected to the battery, the voltage on the battery being increased to any amount required to charge the cells. This does away with boosters and wasteful resistance. It is a great improvement for shipboard, as it has always been necessary heretofore to run the dynamo all day to charge the batteries, even though they form but a small load for the plant. The machine is exactly the same as other multipolar dynamos, the only difference being in the method of connecting up. It works on the same principle as their larger dynamos used in connection with feeder and main and elevator systems.

Fig. 2 shows the new type Rushmore pilot house projector. The same apparatus is made with a tall base for mounting on deck, while the 24-inch and 30-inch sizes built for the navy have two small motors in the base with wires leading to a distant controller for swinging the beam in any direction.

The Victor Telephone Mfg. Co.

The above-named company made its bow to the telephone public at the second annual convention of the Independent Telephone Association, having secured parlors D and E at the Palmer House, immediately adjoining the convention hall. On account of the company having been organized but a short time, the exhibit was not as complete as might be wished. The apparatus shown, however, gave all callers an excellent idea of the high grade of apparatus now ready to be put on the market by the Victor Manufacturing Company. This company does not enter the field of manufacture with new and untried apparatus, but has the advantage of years of experience and practical knowledge on the part of its engineers. The company will manufacture only one grade of apparatus, and that the best, incorporating in it the many details of construction found to be either necessary or desirable in apparatus of this kind.

The company some time ago equipped its factory at 166-174 South Clinton street with all necessary tools and appliances to produce a superior line of exchange and line equipment of every description, from the smallest 16-drop switchboard to the largest exchange equipment capable of taking care of 3,000 or more subscribers.

Other apparatus of the company's make will shortly be fully described and illustrated. A few words of the personnel of the company may prove of interest to our readers. Mr. W. T. Blaine, the general manager of the company, is a business man fully competent to take proper care of the many details entering into the operation of such an industry as the Victor company bids fair to have within a short time, orders already received being sufficient to keep the factory going full force for some time. Mr. E. E. Yaxley is a telephone engineer and expert of some twelve years' experience in both the theoretical and the practical field, and his knowledge of the requirements of the business will do much towards enabling the company to supply successfully the demands of the independent telephone field.

A Successful Boiler Compound.

ONE of the greatest annoyances to the central station manager and attendants of boilers has been the scale forming on the inside of their boilers. This nuisance, which is frequently unavoidable on account of the quality of the water used, is a most objectionable feature, as it forms a non-conducting body between the iron and water, resulting in a loss of fuel. Many compounds have been placed on the market within recent years to remove this dangerous scale from boilers, tubes and flues, but it must be admitted that the majority have proved unsatisfactory. A very successful compound, however, and one which, by practical investigations on a large scale and on the strength of the reports of a large number of stationary engineers, has fully justified the claims of its manufacturers, the Boiler Expurgator Company, of 113 Dearborn street, Chicago, Ill., is called the "Boiler Expurgator." It removes incrustation from either salt or fresh water, eliminates all foreign substances held in solution, keeps the heating surface clear of incrustation, and effects a material saving in the consumption of fuel. It is galvanic in its action and is easily applied, this being done only when a washout is made. It will prevent foaming and allow the boiler to be run a longer time between washouts. The expurgator is in use in

numerous plants throughout the civilized world and the business of the company is steadily increasing. The selling agents are: William Lambert, San Francisco; Caldwell Bros., Tacoma, Wash.; Hendrie & Bolthoff Manufacturing Company, Denver, Colo. Besides the expurgator, the company manufacture engine and cylinder oil filters, which will be sent to anyone on a 30 days' trial with full instructions for use, and if not satisfactory can be returned at the end of the trial. Prices, literature and details will be cheerfully furnished by the company.

Davidson Vertical Triplex Pump.

THE well-known firm of M. T. Davidson, manufacturers of improved steam pumps and hydraulic machinery, whose principal office and works are located at 43-53 Keep street, Brooklyn, N. Y., with branch offices at 133 Liberty street, New York, and 30 Oliver street, Boston, Mass., have within recent years brought out a great variety of electrically driven pumps. One of their latest and most improved patterns is the vertical

factured by the firm has lately been issued and will be sent to anyone on application.

Scaling Down General Electric Stock.

The directors of the General Electric Company, at a meeting held last week in New York City, voted to recommend to the stockholders a reduction in the share capital of the company, both common and preferred, of 40 per cent., so that each holder of 100 shares of present stock will get 60 shares of the new stock. An official statement says: "This settlement, while satisfactory to the common stockholders, is regarded as particularly favorable to the preferred shareholders, inasmuch as it will render unnecessary the taking of any steps for the liquidation of the company, in which event the preferred stockholders would receive only the same amount as the common stockholders and no back dividends. The plan now adopted contemplates the payment, from the surplus earnings of the company as they are hereafter made, of the accrued dividends on the preferred stock.

DAVIDSON VERTICAL TRIPLEX PUMP.

triplex pump, illustrated below, which was designed to operate in connection with an electric motor, by belt connection, or gearing from a line of shafting. The cranks of the pump are so set that the plungers are brought on the water column without shock from the reverse stroke, thus insuring an even and steady delivery. The workmanship and material employed are the very best attainable and each machine is thoroughly tested before it leaves the works. The pumps are made in five sizes, with delivery capacities ranging from 10 to 112 gallons per minute at a speed of 75 revolutions per minute and horse power ranging from 1.1 to 11.7.

Various types of motors are supplied with the machines, the C. and P. ironclad motor being preferred on account of its special design for heavy duty. As will be seen on the engraving, the field coils are square-shaped and the pole pieces project inwardly from the massive field frame. The motor is well ventilated, strong and supplied with self-oiling bearings.

A large number of these outfits have been installed by the firm and have given entire satisfaction everywhere. A new catalogue describing the numerous types of pumps and condensers manu-

On the basis of the new capitalization \$1,275,000 will be required annually to pay 7 per cent. upon the preferred stock and 6 per cent. upon the common stock."

The stockholders will act upon this proposition for a readjustment of the company's capital stock at a special meeting which has been called for August 10, at noon, in Schenectady. The outstanding stock is: Common, \$30,460,000; preferred, \$4,252,000. Under the proposed reduction it would amount to \$18,276,000 common and \$2,551,200 preferred.

UNITED GAS IMPROVEMENT COMPANY, of Philadelphia, Pa., are making extensive additions to their gas-producing plant. These plants are known as the 25th Ward and the Point Breeze locations. At the 25th Ward Gas Works they are building a new scrubber house, 45 feet wide and 120 feet long; a purifier house, 86 feet wide and 180 feet long. At the Point Breeze Works they are erecting a new boiler and engine room, 220 feet long and 55 feet wide; a condenser building, 40 feet wide and 105 feet long; a purifier building, 86 feet wide and 180 feet long; a generator house, 100 feet wide and 184 feet long; a

meter house, with additions for exhaust and valve room, having a width of 70 feet and a total length of 223 feet. All of these buildings are of steel frame construction, brick side walls and slate roofs, supported on metal purlins carried by clear span trusses. All the structural steel work for this extensive plant is being furnished and erected by the Berlin Iron Bridge Company, of East Berlin, Conn.

Housatonic Co.'s "Ideal" Shadeholder.

THE Housatonic Company, of Wallingford, Conn., with office at 253 Broadway, New York City, have just put on the market a new electric shade holder called the "Ideal," and anyone interested in an article of that kind should examine it before placing his orders. It fits every socket perfectly and is very easy to apply, as it will slip over the end of any socket without having to take the screw entirely out. It is made in one

HOUSATONIC "IDEAL" SHADE HOLDER.

piece, insuring rigidity, and there are no parts to work loose. It is very nicely ribbed throughout, giving it great strength and also ornamentation. The adjustment is perfect, as the lamp is always held in the centre. It has the largest capacity and also the smallest adjustment. Circulars and information will be furnished on application, and it is suggested that prices be written for, as they will prove interesting at once.

Knapp Motor and Gordon Cell Outfits.

The splendid fan outfits consisting of Knapp fan motors, manufactured by the Knapp Electric and Novelty Company, of 47 Warren street, New York, and the Gordon cells, manufactured by the Gordon-Burnham Battery Company, of 594 Broadway, which have previously been described in our pages, are meeting with universal favor and the most satisfactory results. The outfit is economical, handy and up-to-date, and the Knapp Company report that their sales of Knapp outfits for June this year are far in excess of the sales for the corresponding month of last year.

Swinging Ball Lightning Arresters.

Every spring and summer season brings a number of new devices for lightning protection. Many of these are on the market for only one season and are then not heard from again. It is probably this fact that gives the Electric Appliance Company great satisfaction in calling attention to the "Swinging Ball" lightning arrester, which has now been on the market for nearly ten years with uniformly successful results. It is made in practically the same way to-day as when first put on the market, showing that the inventor evidently succeeded in producing a satisfactory device. The Electric Appliance Company, as general Western agents for the "Swinging Ball" lightning arrester, carry a large stock in Chicago, and reports that each year brings an increased sale of this specialty.

THE WARREN-MEDBERY COMPANY have about completed the addition to their works, at Sandy Hill, N. Y., and are setting up some very heavy machinery, to be used in the construction of their inductor alternators. The sale of these machines is steadily increasing and the works are running to their utmost capacity. The line of knife switches which they are producing is very extensive and the demand is rapidly improving.

Harrison Safety Boiler Works.

Quite in conformity with all their other literary productions the Harrison Safety Boiler Works, of Philadelphia, Pa., have issued a very handsome and exhaustive catalogue, illustrating the Cochrane separators and appliances for removing liquids or solids from steam and other vaporous or gaseous currents. The catalogue is amply and beautifully illustrated, showing the various portions of the separator, the numerous styles manufactured by the company, complete price lists and users of the separators for live and exhaust steam, compressed air, ammonia gases, etc. The catalogue is well indexed and will be sent to anyone on application.

The Massachusetts Fan Company.

The above company, located at 63 State street, Boston, Mass., have just issued a very complete catalogue illustrating the Davidson ventilating fan wheels and other forms of ventilating apparatus for use in mills, schools, public buildings and general ventilation. Many different styles of Davidson fans are illustrated and the particular advantages of the blades, frame, self-oiling bearings and other excellent features are pointed out. The Davidson fans are said to be very economical, strong and noiseless, give uniform delivery and create no back draft. A number of direct connected fans with various styles of motors are shown, as well as one direct connected to a steam engine. The back pages of this interesting catalogue are taken up with illustrations of various well-known public buildings in which the Davidson fans have been installed.

Zimdars & Hunt.

The general catalogue of Zimdars & Hunt, the well-known manufacturers of high grade electric light and power specialties, 127 Fifth avenue, New York, has just made its appearance. This catalogue includes under one cover the three special catalogues recently issued by this firm and which have been noted in these columns. The catalogue is divided into three sections, A, B and C, corresponding to their three special catalogues bearing these letters. Under Section A we find illustrated and described all types of this concern's well-known knife switches, lugs, connections, instrument switches, switchboard fittings, etc. Under Section B are treated their high grade panel boards, feeder boards, etc. This section has special value from the fact that up to the time of the issue of this section no complete and comprehensive catalogue bearing on these subjects has been available. The information to be found herein is very complete. Section C is given up entirely to the well-known automatic switches and motor starters of their manufacture. A great variety of types are shown for pump, elevator, crane and such work.

The cover is in imitation of marble with copper embossing, and is very handsome in appearance.

The catalogue as a whole is very complete and should prove of great value to engineers, contractors and supply men. It can be obtained by addressing the above firm.

A Useful Data Sheet.

Mr. George Kirkegaard, 28 State street, New York, has compiled and published what appears to be a very useful machinist's and draftsman's data sheet. It is designed to save time in machine shops and is intended to go directly into the hands of the workmen at the bench, who will tuck it up in front of them or on the cover of their tool chest. Mr. Kirkegaard, being a practical man, has observed the need of such a thing and has selected with great care the information most frequently needed by the mechanic. A number of the tables are quite original, as, for instance, the one giving the size of drill for tap holes, which is not to be found in any pocketbook. This data sheet is believed to be a great money saver to all mechanics, as it will save them a great deal of time. The price of the data sheet on heavy paper is 15 cents, on cardboard, 25 cents, and a discount will be

quoted by Mr. Kirkegaard to anyone wishing to order the data sheet in quantities.

I. P. Frink.

The great church light patent reflectors and chandelier reflectors manufactured by I. P. Frink have won such universal favor among architects and engineers that this firm can point to the proud record of having lighted over 20,000 churches. The reflectors have also been installed in large numbers in halls, theatres, art galleries, stores, store windows, banks, schools, hospitals, office buildings, public buildings, etc., for which purpose they are admirably suited. A booklet on light and estimates will be sent free to anyone on application to I. P. Frink, 551 Pearl street, New York.

ADVERTISERS' HINTS

THE WHEELER REFLECTOR COMPANY, Boston, Mass., say the connecting link from sunset to sunrise is found in their reflectors, which are designed for every kind of lighting.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., advertise four styles of transformers for power transmission service. These are the self-cooling oil filled, self-cooling dry, dry with auxiliary air blast cooling device and oil filled with auxiliary water cooling device. They build them in units of any size and for any ratio of voltage.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, Ill., say the swinging ball lightning arrester has the longest record of unbroken success of any arrester on the market and that where properly used it never fails.

THE WESTERN ELECTRIC COMPANY, Chicago and New York, advertise iron armored, brass armored and plain interior conduit, conduit fittings and conduit tools. Their stock is large and their prices are pleasing.

THE ELECTRIC GAS LIGHTING COMPANY, 192 Devonshire street, Boston, Mass., claim the "Samson No. 2" battery to be without a peer for telephone use.

ZIMDARS & HUNT, 127 Fifth avenue, New York, have just gotten out their new catalogue of electric light and power specialties. Better send for it.

SAMUEL MANKOWITZ, 141 South Clinton street, Chicago, Ill., is manufacturing weather-proof wire which he guarantees to be a high grade article at a low price.

BIBBER-WHITE COMPANY, 49 Federal street, Boston, Mass., announce that they have acquired by purchase all rights, title and interest in the stock, tools, factory and good will of the the American Electric Company, of Boston, the manufacturers of the "New Era" and "Victor" burners. A large stock will be constantly kept on hand, facilitating prompt shipments.

THE PHOENIX ELECTRIC TELEPHONE COMPANY, New York, call attention to the thorough equipment of their large factory for the manufacture of telephones and telephone apparatus.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburg, advertise transformers in units of any size.

WESTERN NOTES

THE CUTLER-HAMMER MANUFACTURING COMPANY, 70 to 82 West Jackson street, Chicago, report that since their consolidation with the American Rheostat Company they have been working overtime in order to meet the demands for their goods; and they have more men in their employ than ever before. Mr. J. G. Hickcox, secretary of the company, says: "We have received large foreign orders, and if the increase in business continues, we shall be obliged to seek larger quarters."

EUGENE MUNSELL & CO., of 117-119 Lake street, Chicago, are sending to their Western customers a very neat blotter, on which are embossed the Cuban and American flags, under which are the words "Victorious on Sea and Land." The

printed matter beneath these words refers to the rapid development of a great business in a great city.

IMPROVED TURN-BUCKLES. The Central Electric Company, of Chicago, are carrying in stock an improved type of turn-buckles, both galvanized and plain, which can be furnished with hook and eye, double hook or double eye. These goods are standardized and constructed with a view of great strength being secured.

MORROW COUNTY TELEPHONE CO., formed recently at Mt. Gilead, O., has an American Express board of 200 drops and 140 subscribers, with 150 miles of toll line. The residence rates are \$12 and business \$24 per year. The capital stock is \$12,000. A. A. Whitney is president; V. Peck, vice-president; H. B. McMillen, secretary and treasurer, and C. W. Schaaf, manager. The company is extending its toll system steadily.

NEW YORK NOTES

J. B. COLT & CO., 3 to 7 West Twenty-ninth street, who for years past have been prominent in the business of making and selling projection lanterns and the like apparatus, announce their intention to close out this branch. They are going to devote their energies more particularly to the sale of acetylene gas generators for the lighting of all kinds of buildings, etc. On account of this decision they are offering special opportunities in price to buyers of projection apparatus, arc focusing lamps, magic lanterns, stereopticons, slides and other accessories.

HEBER WELLS.—Many of our readers who manufacture electrical machinery are interested in pattern letters and figures for the various parts of patterns used in the course of manufacture. In that line Mr. Heber Wells, 155 William street, this city, carries a large and varied stock. He informs us that one of the most skilled machinists in this country, after trying many styles for the numbering of patterns, has chosen the Doris as the best general figure. The face is rounded, and the figure draws from the sand with less breaking down than any other style.

No. 532.

A Few Interesting Pointers Concerning Enclosed Arc Lighting.

BY J. H. HALLBERG, E. E.

THE purpose of this article is to call attention to the fact, that much trouble is experienced in connection with enclosed arc lamps, that could be avoided if the men that sell, install, trim and take care of these lamps knew more about the operation of their mechanical and electrical details.

I do not excuse the manufacturers of these lamps, as they often place their goods on the market without being perfectly sure they come up to the claims they make for them. All readers who more thoroughly understand the designing and manufacturing of arc lamps and other electrical apparatus, well know that it is impossible to design them correctly without the practical experimenting. Some manufacturers succeed better than

others in overcoming the constantly arising troubles and ever-changing conditions under which these lamps are to operate.

The enthusiasm of the American designer and manufacturer is the cause of these goods being on the market before they are perfected. Everybody wants to be the first or next first in getting out new designs and current-saving lamps. One thing is sure, it is the best way to find out the weak points, and if it does not prove too expensive for the manufacturer and too troublesome for the customer, this kind of experimenting and testing enables the designer to produce a practical lamp that could not be obtained in any other way in so short a time, without an enormous expense.

Persons interested in the electric arc light business sometimes have ideas of their own which they wish to apply to a lamp sent for a test. This should never be done until the test is completed and you know how the lamp works with the adjustment set at the factory. You should not forget that when you overcome one trouble by a slight change you often run into much worse trouble and sometimes entirely disable the lamp. If you think

your idea will bring you some money buy a lamp and experiment with it. If not, it would be much better for you and the manufacturers if you inform the latter of your idea and ask them to try it for you; it would save you trouble and time.

I will not argue the troubles that may show in any improperly designed lamp, as it would be of small benefit to the men who take care of the lamps. Sometimes much trouble will arise if the lamps are not adjusted for the proper voltage, amperage and alternations. In ordering, always state voltage, amperage, style of cover, finish, color of inner and outer globes, and, if for alternating current work, state alternations per minute; if for street railroad or power circuits state maximum, minimum and average voltage.

The following figures will show you how a properly designed enclosed arc lamp may be completely ruined by too heavy a flow of current at the arc, or by the arc being too close to the neck of the inner globe. This is the most frequent cause of trouble.

Let us now pay attention to Fig. 1. Here we have a diagram of a properly trimmed 5-ampere, enclosed arc lamp connected to a 110-volt, direct current lighting circuit. F is a double pole fuse block with 6-ampere fuses; S, double pole switch; A, ammeter in series with the lamp; R, resistance in canopy of lamp, in series, showing clip connecting it at the proper place with S. M., the solenoid or magnet coil; C, gas cap or gas check to prevent inlet of air in the inner globe; K, upper carbon sliding freely through a hole in C; L, lower carbon, which is firmly held by thumbscrew in lower carbon holder, which is connected to the negative wire from switch; V is a voltmeter, which is connected to the upper and lower carbon and gives us the voltage at the arc, N.

If we now turn the switch, S, the lamp draws its arc, N, the top of which should always be one-half inch from the bottom of cap, C. We will then wait about ten minutes before taking our actual volt and ampere readings. It requires about ten to fifteen minutes for the current to heat the resistance and the solenoid, and it takes the arc about the same length of time to heat the carbons and consume the oxygen (air) in the inner globe, which should make good, air-tight joints at the top with cap, C, and at the bottom with the lower carbon holder. If we now watch the ammeter, A, it will vary in a good practical lamp from $4\frac{3}{4}$ to $5\frac{1}{4}$ amperes. The voltmeter, V, should read about 78 to 80 volts. If V goes over 80 you can bring it down by moving the clip on the resistance to the right, so as to cut in more of it; if V is lower than 78, move the clip to the left. Never move the clip unless you know your line voltage is at the proper pressure and after you have watched the voltmeter for at least five minutes, as it may only be a momentary flash of the arc caused by impurity in the carbon.

We have now data for Fig. 1, as follows: Line, 110 volts direct current; A reads 5 amperes; V reads 80 volts.

The arc, N, is about $\frac{3}{8}$ inch long and $\frac{1}{2}$ inch at least from cap C. If the upper carbon is 12 inches by $\frac{1}{2}$ inch, lower 5 inches by $\frac{1}{2}$ inch solid highest grade carbon, and we let the lamp burn without interruption of the current, it should burn about 170 to 180 hours, and then cut itself out and leave the upper carbon in the position shown by line O, and the lower carbon at line H. If we now remove the inner globe, we will find that the dust accumulated on its inside will wash off easily in clean water. After cleaning the globe, we retrim the lamp, cutting the carbon stub left in the upper holder for the lower by cutting it to 5 inches. If the trimming is properly done we will obtain just as good a light and readings as during the first run; and if you clean the working parts of the lamp once or twice a year and always use highest grade carbons of correct sizes, and never use cracked or chipped inner globes, your lamps should last you a very long time. If we could always be sure the above details were followed out, everything would run along very smoothly, but this is impossible unless a set of very strict rules are laid out for the men who take care of these lamps, and they should thoroughly understand their working parts, especially the mechanical. I have found that much trouble is caused by defects in lamp mechanism, which in turn cause the coil, resistances, fuses, etc., to burn out. These mechanical defects may exist in the lamps themselves (often called their diseases), or may be

caused by improper packing, installation, trimming, etc.; or, after the lamp is hung properly, by the use of bad inner globes, by poor quality of the carbons, by carbons that are not of the right size, by excess voltage at the terminals of the lamp, or by dust accumulating, and in that way preventing the proper working of the mechanical details in the lamps.

If we again turn our attention to the accompanying figures we see in Fig. 1 a properly trimmed lamp with the arc and lower carbon in proper position, and it should burn 170 to 180 hours continually. Fig. 2 shows us an improperly trimmed lamp with its arc and lower carbon too high in the inner globe. Fig. 3 shows us the result of a slight oversight in the trimming.

Let us now retrim the lamp in Fig. 1, so as to bring the arc N in the position shown in Fig. 2. In this case you will notice how the lower carbon L was broken and a small stub J was stuck in the bottom of the carbon holder and through carelessness was not removed. This prevented the insertion of the lower carbon L, which, of course, brings the arc N very near the gas cap C, which is mostly made of metal and soon gets heated above the normal. If the arc should catch in the cup C, it would melt a portion of its metal. That causes a practical short circuit across the arc N, which now drops very much in resistance and allows 50 to 60 per cent. more current to pass through the coils, etc., unless the fuse blows, which seldom happens, as I find that most 5 ampere lamps are fused with 7 to 10 ampere fuses which sometimes carry 10 to 15 amperes. This metallic arc of very low resistance is inclined to flame, and being much above the normal length and heat, touches the neck of the inner globe, as shown in D Fig. 2. If the arc continued in this position it would strain the globe around the neck and sometimes melt the cap C and buckle the globe at D Fig. 3, which leaves the opening E. If we do not pay attention to the lamp and shut it off when this disastrous arc establishes itself, which is easily observed, as the arc has a greenish color and does not give much light, the lamp will, in most cases, be rendered useless. If the lamp should continue to burn, the inner globe will have a film of yellow dust on its inside which will shut off 50 to 75 per cent. of the light. The air will be admitted to the inner globe through the opening E, Fig. 3. This will allow the arc to consume the carbons in 25 to 50 hours. You will also notice how low the arc burned before it cut out. It buckled the globe at I, burned the upper carbon to a point K and the top of the lower carbon G is extremely low, so low in fact that its heat may ruin the lower carbon holder. Should we now have the voltmeter and ammeter connected to the lamp trimmed as Fig. 2, the following readings will be observed: amperes, 10 to 15; volts at the arc, 5 to 10.

As the lamp is only designed to stand 5 amperes, it seems natural that something should give out when 10 to 15 amperes are forced through it.

If we now proceed to examine a lamp which has been subjected to this rough usage, we may find in the worst cases something like the following: After removing the lamp cover and the outer globe, our attention is called to the inner globe, which is generally melted so badly as to be useless. The upper carbon sticks in its passage through the hole in cap C, as it has been roughened from the excessive arc heat, shown in P Fig. 5. If some kind of an insulating compound has been used on the solenoid or magnets it is generally found deposited all over the mechanism, making it sticky. The solenoid or magnet is in most cases burned out. The resistance is generally in a fair condition, but sometimes it has been heated to so high a degree that its own tension pulls it apart. If other insulation than porcelain, mica and lava is used, it will be found charred and useless. The worst trouble of all is, many people who handle the lamps are at a loss to know what caused this disaster. The best remedy in a case of this kind is to send the lamp to its manufacturers and get them to repair it. Should you feel inclined to do it yourself, a few suggestions here may not be out of place.

Remove all working parts from the lamp, soak them in benzine or similar fluid that will cut the insulating compound deposited on them; remove the resistance wire, solenoid and all charred insulation. Clean the lamp frame carefully so that no sticky substance will remain on it. Take a round file and file a hole P in the gas cap C Fig. 5, so that it will give easy passage for the upper carbon, as shown in Fig. 4. Now assemble the lamp. Put in new resistance wire or turn the old one around. This may be done in some makes of lamps as they supply more

than necessary. Screw on the new solenoid. Put in new insulation where necessary, assemble all the working parts and take good care that all joints are clean and work freely. Be sure to clean the dash pot if the lamp has one. Never use oil on the bearings or glycerine on the dash pot, unless so instructed by the manufacturer of the lamp. Place the carbon in the upper holder and be sure the clutch is adjusted, so as to allow it free passage when the mechanism is at rest. Now lift up, or press down on the core in the solenoid and see if your clutch grips the carbon properly and allows it to be lifted as high as it should go. Place the carbon in the lower holder and take a new inner globe and place it on the lamp. Be sure all connections inside the lamp are made correctly and tight. Connect lamp in a circuit, carrying the same voltage as that on which lamp is to be operated, and proceed to adjust lamp by moving the clip on the resistance. The proper place for this clip is determined by a voltmeter, which is connected across the arc (that is one wire makes contact with the upper and the other with the lower carbon). The voltmeter reading should not be depended on unless the lamp has burned 10 to 15 minutes, and should then read according to line voltage as follows: Line—100 volts, arc voltage should not be over 75 volts; at 105 volts, about 78 volts; at 110 volts, 80 volts; at 115 volts, 82 volts; at 120 to 125 volts, 85 volts. The reason for this change of arc voltage is the necessity of a certain amount of pressure in the resistance that is required for the proper regulation of the lamp mechanism.

Sometimes people have asked me why they can't run their enclosed arc lamps on an 80 volt constant potential dynamo without resistance, which would save about 150 watts per lamp. I always tell them that as yet it cannot be done practically. It would require a very expensive lamp and it would be so delicate in its operation that the slightest abuse would prevent its proper operation.

After you have properly repaired, cleaned and tested the lamp, your next move will be to hang and connect the lamp in the circuit on which it is to be operated. Be sure your fuse for a 5 ampere lamp blows at about 6 and not over 7 amperes. Get your positive wire in its proper binding post. A very easy way to determine if your lamp is burning "right side up" or "upside down," is to let the lamp run about 5 minutes, then shut it off and see which carbon is the hottest. The upper carbon should have a red heat, when the lower carbon shows no such sign, if the lamp is properly connected. Should the lower carbon show more heat than the upper, reverse the connections leading to the lamp. The above suggestion in regard to proper connections only applies to lamps operated on direct current. When an alternating current lamp is used this precaution is not necessary.

Everybody who may read the above will surely see how little mistakes and oversights may cost the consumer and manufacturer a great deal of money and cause inconvenience to customers of electric light plants.

The Northern Electric Company of Baltimore, Md.

THIS company succeeded last October to the plant and business of the old United States Electric Power and Light Company, and is operated under the management of J. F. Morrison, who organized and managed both the other companies until they passed into the hands of outside capitalists.

Since the change in the management a new building of brick and iron has been erected. This was put up over the old wooden structure when the latter was removed, all the work having been done while the plant was in operation. The plant is devoted to commercial lighting and power, and is now running 500 arc lights of the Walker type, and 4,000 incandescent lights, with a large number of motors.

This is regarded as a creditable showing, as the new company started in October with only a few arc lights, no incandescents and no power motors. Among the recent contracts are 108 arc lights for a bicycle racing track, recently erected by the League of American Wheelmen, together with two pleasure resorts nearby.

The original power equipment of this station consisted of two Wetherell-Corliss engines, one of 225, the other of 100 h. p., from which power is transmitted by belts to a countershaft, and from this, belts drive eight 50-light and three 100-light American Fort Wayne machines, and two 150 k. w. and one 360 k. w. Stanley alternators. The alternating current has a tension of 2,000

volts, while power for motors is supplied from 220-volt, direct current Walker dynamos. Recently there has been added an American Ball cross-compound engine of 360 h. p. This engine is one of the latest designs turned out from the Bound Brook Works of the American Ball Engine Company. It is provided with a self-oiling device, actuated by a small pump, by which the oil is delivered to the bearing in a jet or stream, governed in its oiling by the speed of the engine. Two additional engines, one of 450 h. p., and one of 360 h. p., are now under contract. There is also a new switchboard, Stanley-Pope design, which will be equipped with all the up-to-date appliances that may be required. The steam equipment of the station consists of six 100 h. p. tubular boilers and one 800 h. p. or the Sterling water tube type. The auxiliary steam equipment consists of two feed-water heaters, of 600 and 1,000 h. p. The fuel consists of George's Creek coal, which is delivered directly to the fireroom by the coal company.

The Waterloo and City Underground Electric Railway, London.

THE second underground electric railway constructed in London will shortly be in full working order, and the conditions of the journey from Waterloo station to the Bank of England will undergo a remarkable transformation. It is nearly seven years since the first electric underground line, the City and South London Railway, which we have illustrated and described on several occasions, was opened; and the improvement that has been effected in the meantime in undertakings of this character is very noticeable. The first line was largely experimental; the second, while it also may be so described in its

MAP SHOWING THE ROUTE OF THE WATERLOO AND CITY UNDERGROUND RAILWAY, LONDON, AND ITS CONNECTIONS WITH OTHER ELECTRIC UNDERGROUND RAILWAYS.

electrical equipment, has, as respects its other features, been carried out with the assurance bred of the success of the first line. The work was begun in June, 1894, and it was expected that the railway would be opened in 1897; but, considering the enormous alterations necessary in constructing the underground station and subways at the Bank, and other unforeseen difficulties, it is surprising that the delay has not been more protracted.

The Waterloo and City Railway is about one and a half miles in length. It consists of two tubes, one for trains passing in each direction, which are some 60 feet underground at the points furthest from the surface. The terminus at Waterloo is immediately below the station of the London and South Western Railway. That station being built on arches, readily permits of the structure beneath, and the difference in level is only about 38 feet, so that lifts are unnecessary. From several platforms steps and inclines lead down to the City lines, and the arrangements throughout appear to be conveniently planned. The lines

of the electric railway terminate in a yard about 350 feet, where there are several sidings.

The generating station, a substantial brick structure, is adjacent to the siding on the west. The sidings are, of course, below the level of the street, as is the floor of the engine and boiler room. After arriving at the station the trains will simply be run on a few hundred feet and be shunted back to the up road in readiness for the return journey. The territory covered by the new railway is shown on the accompanying map. For some distance it runs under the District Railway and from 45 to 53 feet below it. The steepest gradients are 1 in 30, down, and 1 in 60, up. During the descent to the river the gradients

MOTOR CAR, WATERLOO AND CITY UNDERGROUND ELECTRIC RAILWAY, LONDON.

of the two tunnels differ, but at the shaft in the river they are on a level for 100 feet, and then rise 1 in 800 for 1,300 feet, and then 1 in 88 to the end of the station, close to the Mansion House. The platforms will be over 300 feet in length and 65 feet below the surface, to which hydraulic lifts will convey passengers.

The contract for the construction of the tunnels was let as a whole to Messrs. John Mowlem & Co., and they began the work by the construction of staging in the river. The staging was 325 feet long by 50 feet wide, connected by a foot bridge with the south bank of the river, but all material has been received and all excavation discharged by river boats. On the stage were engines and dynamos, air compressors and other machinery necessary in the prosecution of the work. It was the starting point for the tunnel shafts, which were driven in each direction. Air locks were required during a part of the work, but when these were no longer necessary, the haulage of excavated material was done by electric locomotives, made by Messrs. Siemens Bros. & Co., and especially designed by them for the work. They were small machines, receiving current from

INTERIOR OF MOTOR CAR, WATERLOO AND CITY UNDERGROUND RAILWAY, LONDON.

an over-running double trolley. The gauge of the line was 18 inches, and the locomotives were capable of hauling a load of 5 tons at a speed of 7 miles per hour.

The internal diameter of the tubes is 12 feet 3 inches, but near the Mansion House station they merge into one, and the diameter there is 23 feet. The tunnels are built up in sections, each section consisting of seven segments and a key, the section being 20 inches in length.

The method of electrical equipment received very careful attention on the part of the company, and the relative advantages

of the three-wire and three-phase systems were the subject of much discussion. Eventually the three-wire system was adopted at the suggestion of Prof. Kennedy, who was appointed electrical engineer, and prepared the specifications. Messrs. Siemens Bros. & Co. were given the contract for the engines, generators, motors, etc., and they have supplied three direct coupled units with generators of their two-pole type, giving 225 k. w. (500 to 550 volts) at 350 revolutions. The engines are three-crank horizontal compound machines, made by Messrs. G. E. Belliss & Co., of Birmingham. The boilers have been supplied by Davey, Paxman & Co., and are fitted with Vicar's mechanical stokers. All rolling stock has been made by Jackson & Sharp, of Wilmington, Del. It consists of motor and trail cars, both of which are shown in the accompanying illustrations. The cars are of American design, and the interior arrangement is similar to that of cars on the New York Elevated Railroad. The motor and trail cars differ in construction. Externally the former much resemble the motor cars in use on the Budapest electric subways.

There is a compartment for the motorman at one end, while the remainder is designed for passengers. Entrance is by the platform at the end, and also by a side door opening directly on to the platform in the usual way. The interior of the passenger compartment of the motor car is shown in the illustration, and the general arrangement of the trail car is similar to it. A pair of steps at the end lead to a raised deck adjacent to the motorman's compartment, and there are seats here for passengers. A very simple but neat finish has been given to the cars, which are lined with oak and fitted with bronze trimmings. The only purely ornamental feature is a small machine-pressed oak beading, with a variation of the egg and dart pattern, above the windows. Only the car bodies apparently have been manufactured in America, the bogies having been constructed at the Eastleigh Works in England. We are indebted to "The Railway World," of London, for material for the above data and illustrations.

The Evolution of the Telephone Line Signal.—II.

BY ARTHUR VAUGHN ABBOTT.

AT first it was considered desirable by lamp manufacturers to preserve a large volume in the bulb of the lamp in order to secure an adequate vacuum. To attain the desired compactness, the bulbs of the lamps were made smaller and longer. Gradually improvements in manufacture were sufficient to reduce the bulb of the lamp to a smaller diameter than that of the screw base, and it at once became apparent that some other method of securing the lamp in its socket would still further contribute to compactness. The next step was the construction of an exceedingly small bulb lamp, which was secured to a wooden base carrying two metal rings, to which the leading-in wires of the lamp were soldered. Whether the theory that the small-sized bulb militates against a sufficient vacuum is correct, or not, it has been impossible to definitely ascertain, but experience has shown that lamps having small bulbs were not so successful as large ones. In order to retain the compactness thereby attained, a long and slim bulb was made.

In this lamp an additional advantage was secured by placing the filament at the end of the glass opposite the seal. This end could be blown hemispherically and quite thin, thus allowing a maximum of light to be transmitted. Lamps of this description were chiefly made for four-volt circuits, the filament consisting of a very thin thread of carbon stretched between two platinum wires. These leading-in wires were fused through the sides of the bulb and soldered to two bits of thin copper forming the contact strips that were cemented to the glass tube. Some difficulty was experienced in the peeling off of these pieces, and, in addition, the amount of platinum in the leading-in wires was so great as to considerably increase the cost of such lamps. So, from motives of economy, a partial reversion toward earlier forms has taken place in the present standard lamp. The bulb is a glass tube about one-fourth of an inch in

diameter and one and one-eighth inches long. For four-volt lamps a straight filament is used, but for all others a horseshoe shape. Only sufficient platinum is employed in the leading-in wire to pass through the glass, and in other respects the general details of manufacture correspond closely to the best practice in standard lamp construction. The base of the lamp is a bit of boxwood, so shaped as to readily enter the springs forming the socket, and arranged to prevent the lamp from turning as it is pushed into place. The earliest lamps were all designed for low voltage circuits, rarely more than four volts. Presently it became apparent that lamps of longer life, together with an economy in conducting circuits, could easily be attained by the use of higher voltages, and the next advance was secured by making lamps for 10 and 20 volts, while at present 12 and 24-volt lamps are standard.

When first used as signals, the lamps were placed in the local of a relay actuated by current passing over the line to which the signal was attached. In the early attempts the ordinary telegraph relay was employed, armed with extra heavy platinum contacts to prevent burning. It seemed possible to obviate the expense of installing and maintaining this relay by an appropriate lamp directly in series with the subscriber's line, so placed that the removal of the telephone from its hook should close the circuit and light the lamp. This experiment was first tried in the Chicago express office, and, on the whole, worked passably well, there being a comparatively small mortality of lamps due to short-circuits and other accidents. A continuation of this experiment was attempted in another office, but resulted disastrously, as the lamps were burned out so rapidly as to cause an excessive maintenance expense. The occasion of this failure is to be ascribed to a preponderance of aerial lines in the last case. A wind-cross occurring near the office on a long line would subject the lamp to an abnormal voltage and either injure or immediately destroy it. In an express office, where the lines were chiefly underground, little or no trouble was experienced from this cause, and in an office in St. Louis, similarly equipped with lamp line signals placed directly on the subscriber's line, the use of a very heavy filament lamp obviated the difficulty experienced with injury to lamps. But while economy in installation, due to the omission of the relay, is eminently desirable, present experience decidedly indicates that the relay is essential to the successful lamp signal.

For this purpose rather an interesting type has been evolved in an attempt to consolidate the relay, lamp and socket into a single piece of apparatus and at once obtain a device which should be absolutely dust-proof and free from trunnion trouble. This relay was developed largely with the assistance of Mr. M. A. Edson, of the Chicago Telephone Company.

The front end of the "lamp relay," as it is termed, consisted of a brass tube forming the lamp socket, carrying the screw at the bottom, supplied with round glass cap, carrying the subscriber's number. From the rear of the socket extends a core of soft iron surrounded by an iron tube, between which the winding space was obtained. A hemispherical brass cup covered the end of the iron tube, retained in its place by an appropriate set screw. The inside of this cap was hollowed out, containing a piece of soft iron, in the form of a frustrum of a cone, that constituted the armature. As this piece of apparatus was set horizontally the armature rested upon its edge in an unstable position, tending to settle backwards and rest against the back of the cap. The excitation of the windings magnetizes the core and attracting the armature, draws it up sharply. A thin platinum spring placed on the front face of the armature serves to make contact with a corresponding platinum point set in the centre of the core. As the core is insulated from everything but one lamp wire, while the other is connected to the cap, the excitation of the relay lights the lamp. By this device a relay was obtained, the moving parts of which were completely dust-proof. All trunnions or hinges were obviated and the armature merely resting upon a sharp edge secures a minimum amount of friction. Notwithstanding the compactness and completeness of this piece of apparatus, it has been found desirable to disassociate the relays and lamps, placing the relays in a case by themselves, away from the switchboard.

Probably the most gratifying feature in the evolution of the line signal has been the improvement in the life of miniature lamps. When the luminous signal was first proposed the question of cost of lamp renewals was at once raised. As each lamp was only illuminated for a few seconds at a time the service

seemed equivalent to constant flashing, and ominous prophecies were plenty as to the short life to be expected. It was confidently asserted that such small lamps would either immediately burn out, or else so rapidly become dim as to be valueless as signals. Some tests were immediately instituted in the hope of eliciting information on these points. There was no question but that the candle power of the lamps gradually declined, and photometric measurements showed that when a lamp failed to emit at least .05 candle power, it became of no value as a signal.

To determine the resistance to flashing, a number of lamps were connected in circuit with a clock pendulum and flashed at intervals one second for nearly a month, with no signs of serious injury. During this test the lamps were illuminated more than a million times, so it seemed certain that a reasonably long life could be expected. Experience has since shown this conclusion to be justified, for in the main office switchboard in Chicago, there are now lamps at work that have been in service for upwards of three years and seem still to be in fairly good condition. Observation has further shown that accidental injury rather than old age, is the cause of most lamp failures.

Much delay was experienced in obtaining the first lot of switchboard lamps, so on reception they were immediately placed in service without inspection. The rapid failure of a large number of these caused no small degree of consternation and it was determined to initiate a systematic inspection. As a result, all lamps are now examined: 1. Mechanically, to see if they will fit the sockets. 2. Electrically, to determine if they have the proper voltage and consume current within the specified limits. 3. Optically, to ascertain if they emit the required candle power and absorb the proper watts per candle. Also a certain number of lamps from each lot are placed on life test and burned to destruction.

Tests made show that in 1895 only 200 hours' life could be expected, while from the latest tests the 20-volt lamps show 2,400 hours' life before failure, and the 10-volt lamps show 2,500 hours, and are still burning, with indications of considerable additional life.

With sample lamps tested in 1897 the 4-volt lamps failed almost immediately, only yielding upwards of 50 hours. The 20-volt lamps, tested in 1897, gave upwards of 600 hours' life as an average. Nineteen lamps tested lasted over 1,900 hours and one lamp over 2,500 hours.

Results indicate a much greater irregularity for the 10-volt lamps. Some make a bad showing, only one lamp lasting over 40 hours; others are much better, indicating a life of 400 hours, but still are much below the life shown by the 20-volt lamps. A curve represents the results of tests upon 20 10-volt lamps, recently manufactured. This curve is a straight line for 2,500 hours, showing that so far no failures have occurred, and from the appearance of the filament, it is reasonable to expect several hundred hours more life.

Some other curves taken illustrate strikingly the relation between life and candle power. As switchboard lamps are usually supplied by 10 cells of storage battery, it is impracticable to always maintain them at precisely a constant potential, for the pressure is likely to vary one or two volts from that of full charge to that of discharge, and regulating resistances are more expensive than decreased lamp life. Even at the highest pressure it is interesting to note that the lamps at present show a life of over 1,400 hours.

Lamp experts will at once infer that improved life is obtained by a lamp of low efficiency and will urge the cost of the current as an insuperable objection. The total cost of a luminous signal is evidently the cost of the lamp, plus the cost of current consumed during its life, and it is easy to show that this is a minimum when the cost of the energy consumed is equal to the cost of the lamp. Switchboard lamps now cost in the neighborhood of 45 cents each. With a life of say 2,000 hours, the cost of energy is about 60 cents, but it has been shown that accidental causes tend to reduce the actual life in the switchboard far below that shown by laboratory tests and it is doubtful if the average lamp lives for 1,200 hours. Unless accidental destruction can be greatly reduced below the present amount, the cost of the lamp is now considerably above the cost of energy during its life, and a still lower efficiency could profitably be employed, for it must be remembered that the thick, heavy filament in the low efficiency lamps is the best insurance against accidental injury. Theoretically, subscribers' line lamps should last 25 years; cord supervisory lamps from one to two years;

trunk line lamps the same length of time, and pilot lamps from three to six months. Such a life as this has been obtained in the cord and pilot lamps, but it is doubtful if the theoretical limit for the line lamps will ever be closely approximated.

Even in the present probably only partially developed state of the luminous signal, nearly 20,000 subscribers are now served upon boards thus equipped, and switchboards for as many more are in process of construction. Already the adoption of this form of signal has materially modified the arrangement and design of switchboard apparatus, and has been so efficient a factor in the improvement of telephonic service that it is difficult to prophesy the end of its effect.

The Chesapeake and Potomac Telephone Company, Baltimore, Md.

BY C. B. FAIRCHILD.

TWO companies are in the telephone business in Baltimore. The Chesapeake & Potomac Telephone Company handles the bulk of the business, however, and were first in this field, the original company having been organized in 1878, to operate under the Bell patents. The Bell solid back instruments are used, and the lines are metallic and of hard-drawn copper wire. The territory covered by this company embraces all of the State of Maryland and District of Columbia, and part of West Virginia. The superintendent, Mr. Archibald Wilson, has been with the company since its organization, and was the first to introduce telephones in Baltimore, having early in 1878 established between his home and that of some of his neighbors what he now calls a play line, a large box telephone with magnets having been employed.

There are two main Baltimore exchanges located on the fifth and seventh floors of the building, which the company owns, on St. Paul street. The number of local subscribers is about 3,600. Eleven branch exchanges are located in different parts of the territory, and there are several private exchanges for the accommodation of railroad companies and other corporations that do a large private business. There are four copper metallic circuits between Baltimore and Washington, a distance of 40 miles, so that subscribers can get communication between the two cities with great facility. For ten years past the company has had connection with the long distance system of the American Telephone & Telegraph Co., the main line of which passes through Tuxedo, six or seven miles from the Baltimore exchange, where they now have an office exclusively for long distance business. By this means any local subscriber can talk directly with a person as far west as Omaha, east to Portland, Me. A metallic circuit is provided in all cases for long distance service. The subway lines occupy conduits of vitrified clay, and commodious and well built manholes are located at the street corners. The conduits also contain a return wire, put in by the telephone company to take care of the stray currents from the trolley lines, and thus prevent electrolytic action on the cable sheaths.

The demand for instruments is increasing rapidly, due to the inauguration of a message rate service, which has been recently adopted, and the system of regular and thorough inspection. This includes calling up each subscriber in the morning to see if the line is in working order, besides having each instrument inspected every 30 days by an expert, at which time the subscribers sign a statement that it is in good order. Batteries are renewed periodically. All complaints are turned over to the trouble department, are promptly investigated, and necessary repairs made, so that a subscriber is sure of getting a satisfactory service.

The schedule of rates has been adopted on the message basis, so that the subscriber pays in proportion to the number of calls he makes, and whether he is on a two, three or four party circuit. This is done to meet the requirements of small merchants, marketmen and others whose business will not warrant the payment of a regular yearly rate. The party lines are so arranged that the operator can call any instrument on the circuit without disturbing the other, by simply pressing a button. The price schedule for message rates is according to the accompanying table. No charge is made for incoming calls, and the rates apply to business places within one mile radius of the exchange, and to residences within two miles. An extra charge for each quarter of a mile beyond the limit is made of \$10 per annum

for a special circuit; \$6 for a two party circuit, and \$5 for a three party circuit:

No. of Local Calls.	Special Circuit Rates.	Two-Party Rates.	Three-Party Rates.	Extra Calls.
600	\$66	\$50	\$42	8 cents.
700	74	57	49	7 "
800	81	63	55	6 "
900	87	68	60	5 "
1,000	92	72	64	5 "
1,200	100	80	70	5 "
1,400	106	86	76	5 "
1,600	112	92	82	5 "
1,800	118	98	88	5 "
2,000	124	104	94	5 "
3,000	150	...	...	5 "

As noted above the Baltimore exchanges occupy a building owned by the company, with suitable offices for superintendent, contract department, electrical and operating departments, while the fifth and seventh floors are occupied as operating rooms, in which 43 operators are employed, with a chief and two assistants, and a monitor operator. These rooms are in charge of Mr. Frank Boyd, chief operator, who has shown great skill in selecting, organizing and managing the force, thus securing an exceptionally fine and reliable class of operators. The switchboards are located on the sides of the rooms, and are designed for 38 operators.

The switchboard is composed of ten sections, and each section has three positions. In each section there are 2,700 jacks, representing 2,700 circuits. These are arranged in groups of 100 (5 strips of 20 each), and these hundreds are placed in four rows of six groups each and one row of three groups. The first group is known as 0, meaning all circuits from 0 to 99 are contained in this group. The next is the 100 group, and contains all lines numbered from 100 to 199; the next 200, and so on. On each section there are 300 annunciators, 100 to each position, and at each position sits an operator. All lines enter the switchboard at the first section, where a jack is looped into the circuit. It then passes to section 2, where another jack is looped in, and then in succession to the rest of the sections, on each of which the jack is introduced, and returns to an annunciator somewhere in the system.

The new board on the top floor has an addition in the form of a miniature lamp, which is lighted and extinguished by the movement of the annunciator. Whenever a call is registered by the drop opening, the lamp circuit is closed and the lamp burns. The moment the operator restores the annunciator to its normal position the circuit is broken and the lamp goes out. The lamp is on a level with the operator's eyes and is intended to warn her that someone is calling.

Each operator controls 100 circuits, 80 of which are classed in the unlimited service, and 20 in the limited. On a call coming from one of the latter, the operator is required to fill out a record ticket, noting the number of the instrument calling, the time in hours, minutes and seconds, and the number of the operator. These cards are collected each hour, and the tolls are charged up by a special clerk. Women operators are employed during the day, and until eight o'clock in the evening, when men come on for the night service, and remain until seven o'clock in the morning. The day operators are on duty nine and one-half hours with one-half hour for lunch, and fifteen minutes recess in forenoon and afternoon. The first shift comes on at seven o'clock in the morning, and others follow at half-past seven, at eight, half-past eight and ten o'clock. Thirteen men are employed on the night service, whose duty it is to watch both boards and answer such calls as may come in. The wages paid to the women operators range from \$5.25 to \$9 per week, depending upon individual skill and length of time they have been in the service of the company. The force is divided into five grades, known as A, B, C, D and E, and great care is exercised in selecting and training the applicants for their positions. Applicants have to come well recommended, and must be reasonably strong and steady of nerve. One-third of the applicants fail to meet the requirements, and never become what is known as skilled operators. This is due to several causes, such as defective eyesight or hearing, but chiefly to lack of that particular deftness which is required. Although the service is considered wearing, the nervous strain being very great, a few operators in this exchange have been in the company's employ for 18 years. In breaking in new operators, they are first stationed behind a

regular operator, with ear receiver in position, so that they can hear all the calls, and watch the movements of the operator. Then, when business is slack, they are given a seat at the board, and the regular operator in turn watches and instructs them in their duty. Applicants receive no pay while under instructions, and not until they are turned in as substitutes. The switchboard is so arranged that the operator can stand up or sit down as she may choose, but the rules require that each one speak in a low tone. They are not allowed to communicate with each other, nor in any case to give information to a subscriber, not even their own names. Should a subscriber wish to make a complaint against an operator and ask for her name, she replies: "I have no name, but my number is so and so." Every precaution is exercised to prevent a subscriber from learning the name of any particular operator.

Once a month a record is made of the number of calls received in a day, when an average is ascertained for each operator per hour, and should it be found that some of them have an excess of calls the circuits are re-distributed to make the work as uniform as possible. The calls usually number about 10 per day for each subscriber, in which case, 3,200 subscribers, the number on the main board, the average number of calls answered per hour per operator would be 93 and the maximum 181.

A monitor operator is employed who is stationed at a separate board, which can be connected with any panel of the main switchboard. It is the duty of this monitor to record the work done by any particular operator. The record shows the time of the call in hours, minutes and seconds, the time the operator answers, the time when connection is secured, and when the circuit is rung off. By studying this record the managing operator is able to judge whether the girls are prompt in answering calls, or if they are indulging in irrelevant conversation with a subscriber.

Visitors are admitted to the operating room on a pass from the superintendent or other official, but in no case are they allowed to communicate with the employes, nor are the employes allowed to receive notes or mail matter at the exchange. In very urgent cases, when a message comes from the operator's home, the chief operator may allow her to receive it.

Each operating floor is provided with a comfortable dressing room for use by the employes, with toilet facilities, and there is a room set apart as a lunch room with tables, where the girls can meet and partake of their lunches. No provisions are provided by the company, but a messenger boy is employed who comes in just before the noon hour and takes such orders for lunches as may be given him, which are filled at a neighboring restaurant. The following are extracts from the code of rules, copies of which are posted in the dressing room, and will indicate how rigid and thorough is the matter of discipline. This is deemed necessary, not only for the protection of the company to secure efficient service, but also to protect the operators from officious attention from undesirable parties:

RULES GOVERNING OPERATORS.

Operators must report punctually at the hours designated by the chief operator.

Operators must be courteous, under all circumstances, to subscribers and to each other.

Operators must not leave the switchboard without permission.

Operators are forbidden to sharpen pencils, manicure finger nails, to eat or read while at the switchboard.

Operators, before entering the operating room, must thoroughly brush their clothing and shoes.

Scarring or marking the switchboard will not be tolerated, and operators are cautioned against the habit.

Operators must enter and leave the operating room with the least commotion; every movement of the operator should be made so as to avoid as much noise as possible.

Operators must not notify each other that they are being called for over the wire; always inform the chief operator when an operator is asked for.

Operators are forbidden to give their names to the public; they must be known by number, never by name.

Operators must cultivate a low tone of voice. Answering calls in a loud voice will not be permitted.

Operators are forbidden to call out "Hello" or "Well," when answering calls; they must use the words, "What number."

Operators must not throw down the cams; they must be pushed down.

Operators must insert and remove the connecting cords by

grasping the plug only; they must never push or pull on the cord.

Operators must leave the circuit as soon as the connection is fully established; listening to connections on the wire is strictly prohibited.

Operators must be careful not to call in on connections while the parties are talking; wait five seconds before calling in.

Signals must be rung out clearly and distinctly, making a distinct pause before repeating the signal. This is imperative.

An operator's sole duty is to answer calls and make connections as promptly as possible, and operators are forbidden to do aught else except by permission of chief operator.

Operators who fail to report for duty on time will lose the day.

When operators are unavoidably absent they must report the cause to chief operator before eight a. m.; failure to do so will be cause for suspension.

Operators who are off duty must report before one o'clock p. m. the day before they expect to return, otherwise their places will be filled.

Operators are forbidden to take messages for each other; all messages for operators must go through chief operator.

Operators must keep posted as to daily orders on bulletin board. Ignorance of orders will not be accepted as an excuse.

Operators will be held responsible for the condition of lines, instruments and switchboard under their care; if they are not in good condition, report them to chief operator daily if necessary.

Operators are reminded that loud and boisterous conduct is not genteel, and they are, therefore, expected to preserve a proper decorum in all parts of the building.

All information to subscribers, etc., must be given from chief operator's desk. Operators must under no consideration give information to non-employees.

Operators will not be allowed to receive mail, visitors or packages while on duty.

No excuse will be accepted for failure to report for duty on Sundays or holidays. Violation of this rule is sufficient cause for suspension.

Conversations over our wires are inviolable. Operators, therefore, must under no circumstances listen on the wires. To repeat conversations that have been overheard is sufficient cause for dismissal.

Operators when on duty are not allowed to leave the building without permission from chief operator or his assistants.

Practical Features of Telephone Work.—XVII.

BY A. E. DOBBS.

THE RECEIVER.

TELEPHONE receivers have not departed greatly from the standard Bell type, except that there is quite a difference in the quality of the material of which they are made. The best quality of steel for example will hold its magnetism for a long period of years; while I have run across some which were worthless in a few months.

I know of one manufacturer who uses steel that costs about 80 cents a pound for his receivers. It is unnecessary to say that his receivers are not sold for 50 cents apiece, and he has customers who have an idea that first cost isn't everything, and that people who buy instruments of him do not have to replace them in a year or so. Good electrical instruments require first-class workmanship and first-class materials, which recalls the advice of Dr. F. B. Crocker in regard to dynamos that "a poorly finished machine is apt to be very inefficient," or something to that effect, possibly because the manufacturer who uses first-class material and good workmen, will also spend the slight amount necessary to give it a good finish.

There is a tendency now among many manufacturers to use receivers of the bipolar type, and some of the latest put out by the Bell company are of this pattern for use in connection with their long distance instruments.

There is also a disposition among some of them, to make the case partly of metal. I do not think this is a good idea for the reason that the person using it is liable to shocks during a storm and this evil is by no means imaginary, as any experienced operator can certify. It is useless to caution people against using a telephone during a thunder storm, for an exchange which has been quiet all day may suddenly receive a large number of calls upon the approach of a storm, and it is precisely in such emergencies as this that the telephone proves

its convenience, and with the many protective devices at our command, there is no need of shutting down an exchange during a storm, or exposing patrons to disagreeable shocks. An exchange should always be ready for business, and every safeguard provided to inspire public confidence. Let, for instance, some newspaper publish an account of a person killed, or shocked, while using a telephone. Hundreds of people read that item and thereafter they cannot be persuaded that a telephone does not "draw lightning."

One company in Cleveland, O., has gone to the other extreme and constructed a receiver in which even the cord tips are covered by the hard rubber case and no metal of any kind is outside; the receiver is of the bipolar type; and taken altogether it is as good as any I have ever seen.

The present practice is generally, to wind the receivers to a resistance of from 75 to 80 ohms, though one or two companies wind them as high as 175 ohms, which gives them a very powerful action, but they have to use a very heavy diaphragm, so that I really cannot see what is gained by it. Besides, as the receiver is connected in series with the line, it seems to me that the extra number of turns and greatly increased resistance and self-induction are a detriment, but it may be that the extra power thus gained will more than offset this feature.

I wonder if anyone has ever tried a receiver wound to 1,000 ohms and bridged across the line terminals?

INSTRUMENT SPECIFICATIONS.

I.—WIRING.

The wiring to be as much as possible in plain sight, and all of it readily accessible, and the wiring of the generator box and transmitter should be so arranged, that they can be readily taken apart for inspection and repairs.

Contacts between different parts of the instrument, as between the transmitter and magneto box, must be made through binding posts with machine threads and screws so that they can be readily disconnected; and contacts made under wood screws and washers, will not be approved unless such contacts are never likely to be disturbed and in addition are soldered.

No wires to go on the back of the backboard except the two leading from the battery to the switch and induction coil.

Induction coils and other parts must be so placed as to be readily accessible for inspection and repairs.

The induction coil must not be placed in the base of the transmitter arm or so placed that the entire transmitter would have to be disconnected in order to get at it, as these coils frequently get out of order.

Wiring contacts in the bell box and transmitter should be soldered as far as practicable, especially those in contact with the binding screws, leaving the connecting wires only to be brought under the screw.

No wires in the box to be coiled or "pig-tailed," except those connecting wires which are liable to be disconnected for tests, etc.

II.—MISCELLANEOUS.

The switch must have firm rubbing contacts, and preference will be given to those having platinum at such contacts.

The ringing coils should have a resistance of 250 ohms and must be so connected to the switch as to be entirely cut out, or short circuited, when the hook is up.

The generator—for ordinary exchange instruments—should ring clearly through a non-inductive resistance of 10,000 ohms, and the armature should preferably be "built up" of laminated plates.

III.—TRANSMITTERS.

Transmitters should be of the Hunning type and constructed as follows:

The disk to have a free swinging surface of at least 3 inches.

The resistance to be as nearly as possible from 15 to 18 ohms. Where granulated carbon presses against the disc, the area of contact not to exceed a square or circular space of $\frac{3}{4}$ -inch in diameter. This also applies to transmitters of the "ball" type.

Any screws used to hold the carbon block to the arm should be insulated from the granules, unless specially intended to transmit part of the current; but it is better to have the current pass from the disk through the granules and to the plate directly, without going through any other conductor than the carbon, and an exposed screw in the base of the carbon block has a tendency to make the transmitter uncertain in its action.

The carbon disc should be electroplated on the front side

and contact with the battery made by means of a fine wire soldered thereto.

The induction coil to be four inches in length, and the iron core to consist of a bundle of fine, soft iron wires, laid longitudinally, not to exceed five inches in diameter, the iron wires not to be larger than 22 B. & S. in size.

The primary coil to be wound to a resistance of 1.5 ohms, and the secondary to 225 ohms, the winding to be as nearly uniform as possible, the difference between any two coils not to exceed 4 per cent.

(The requirements as to the secondary winding may be varied according to circumstances, but whatever winding is decided upon, make all the others conform to it).

There should also be a spring washer in the hinge of the arm, to insure a reliable battery contact at this point. (The author has traced a great deal of trouble in the battery circuit to this hinge).

To get good results the battery used with this transmitter should deliver .2 of an ampere through the transmitter, switch and coil.

Overhead and Underground Telephone Work, Stockholm, Sweden.

ONE of the most interesting telephone cities in Europe, at least one to which a large amount of attention has been drawn, because of the alleged cheapness of the rates, is Stockholm. We have from time to time referred to the work in that city, and one of our articles illustrated and described the terrible damage done by a wind and snowstorm which broke down the huge roof structures for carrying wires and also leveled the suburban pole lines for miles. The result was a serious and prolonged interruption of service, and the determination of the telephone company to imitate American telephone companies by putting its wires underground. The work is now being proceeded with, and we illustrate one of the large concrete subways now being laid. These subways are made in sections of various sizes and number of ducts, from main lines with 60 and 76 ducts,

REPAIRING OVERHEAD TELEPHONE LINES, STOCKHOLM, SWEDEN.

down to branches and minor lines with tubes of only 7 ducts. By way of contrast we show the Stockholm method of inspecting and repairing overhead telephone lines, involving the use of a traveling car which crosses the lines over the roof tops and

streets and thus enables close inspection to be made of all the conductors. The expense involved in laying the underground

LAYING TELEPHONE SUBWAYS, STOCKHOLM, SWEDEN.

subways is very heavy, and naturally adds greatly to the fixed charges in the operation of the telephone system.

The New Veeder Cyclometer Factory, Hartford, Conn., Electrically Operated.

WE illustrate herewith a novel and interesting machine shop designed and built by the Berlin Iron Bridge Company, of East Berlin, Conn., for the Veeder Manufacturing Company, of Hartford, Conn., who are noted for the excellence of the Veeder cyclometer, which is one of the best instruments made for recording distances traversed by bicycles. The mechanism of these cyclometers is very fine, and in the different processes of manufacture it requires the best of light in carrying on the various operations. The business of the Veeder Manufacturing Company being largely on the increase, they decided to build an entirely new plant, and the illustrations herewith show their new machine shop, both externally and internally.

The first illustration shows the exterior of the building, which is of a somewhat novel construction. The supporting framework is entirely of steel, the greater portion of the construction being steel and glass. It is three stories in height, the exterior presenting a very ornamental appearance from the unique character of the construction. It is 30 feet in width, 110 feet in length, the three floors giving nearly 10,000 square feet of floor surface, every inch of which, owing to the well-diffused light in the interior of the building, can be occupied for manufacturing purposes.

The interior is heated by hot air forced into the interior of the building from an adjoining boiler room by means of ducts located and made a part of the supporting columns of the building. This peculiar feature of the building was designed by C. H. Veeder, the president of the company, and adopted by the Berlin Iron Bridge Company in their design. Particular notice is

called to the sides of the building, which are made almost entirely of glass, but arranged in sections so that they can be easily opened and closed, thus securing plenty of fresh air. A great many people have an idea if the sides of a building are made of glass that the interior in warm weather will be insufferably hot, the same as a greenhouse. The facts of the case are exactly opposite. Owing to the superior ventilation secured by means of every other panel of glass swinging on a centre pivot perfect ventilation may be secured, and thus instead of being ex-

FIG. 1.

ceedingly hot in warm weather it is extraordinarily cool, and pure, clean air from the outside is furnished for the workmen.

Fig. 2 shows the interior of the upper floor of the building. This floor is entirely clear of columns, the roof trusses being of sufficient capacity to support not only the roof loads, but also to carry shafting, pulleys, etc. Particular attention is again called to the lighting of the interior of this portion of the building. A large amount of glass admits and diffuses the light so thoroughly in and through the interior of the building that the very fine work of the Veeder cyclometers can be carried on in the centre of the building as well as on the outside. The building is a credit to the designers—the Berlin Iron Bridge Company—to whom we are indebted for the illustration.

The current both for power and lighting is obtained from the local Electric Light and Power Company at the pressure of 220 volts, two-phase. The 110-volt lamps are distributed by the

FIG. 2.

ordinary three-wire system, the numbers on each phase being about equal.

Power is furnished from General Electric two-phase induction motors. A 5 h. p. specially wound motor is used to run the elevator, the motor being directly belted to the hoisting mechanism and reversed by a special switch. In order to avoid excessive currents in the armature winding when starting, the end connections in the armature winding are made of high resistance metal. Some trouble was found at first on account of the excessive momentum of the armature, but a flange pulley was placed on the armature shaft and the belt allowed to run sufficiently loose that the belt can slip on the armature pulley when the hoisting mechanism is stopped quickly. This arrangement has been in use several months and gives no trouble.

Work of The Electrical Engineer Institute of Correspondence Instruction.

IT is exceedingly gratifying to note the success which has attended the conscientious efforts of The Electrical Engineer Institute of Correspondence Instruction in its attempt to furnish to the profession of electrical engineering absolutely reliable and trustworthy instruction.

Since the organization of this Institute in the early part of the present year, every State and Territory of our country, as well as many foreign countries, has furnished its quota of students, who have hailed with many a kind word of appreciation, the advent of the system which is rapidly proving to be almost ideal in its treatment of engineering subjects, and particularly those involving the manifold applications of electricity.

No doubt much of this success must be attributed to the standard set by the Institute which, we feel safe in saying, cannot be surpassed, since such eminent authorities as Professor Francis B. Crocker, of Columbia University; Charles F. Scott, the Chief Electrician of the Westinghouse Electric and Manufacturing Company; Elmer G. Willoughby, the well known electrical instrument expert; William Maver, Jr., the celebrated authority on telegraphy; Thorburn Reid, the well known designer of electrical machinery, and many others are included among those who have prepared papers for the courses of the Institute.

The student is thus assured of a course of instruction, the like of which even some of the universities of the country would find it impossible to supply him with. This fact has found keen realization in the electrical engineering profession, and is exemplified on the rolls of the Institute in a manner strikingly characteristic of the ambition and ardor existing among those engaged in the profession and trade. Many a man whose attainments stand unquestioned in the profession has found it advantageous to enroll as a student, thus enabling him to refresh his mind on subjects long forgotten, as well as to bring himself fully up to date in the latest developments and practical applications of his profession.

Students and others who have investigated the methods of the Institute and examined its series of instruction papers have expressed their complete satisfaction with its methods and its work. The Institute has in this manner gained a large circle of friends almost immediately, and this circle seems to be ever widening. Many manufacturers of electrical apparatus have recognized the value of these courses of instruction to their employes and have consequently afforded the Institute every facility in their power so that its representatives might present to their employes the methods of the Institute. As a consequence students have been enrolled in most of these manufacturing establishments, and the list is growing daily.

It is most gratifying to note, however, that not alone is the workman and apprentice enrolling, but the employer himself, as well as his immediate subordinates, appreciate the opportunity offered them and in many establishments therefore the several departments of office, storeroom, machine shop and power house have contributed students to the rolls of the Institute.

We have no hesitation in prophesying for The Electrical Engineer Institute of Correspondence Instruction a continued and growing usefulness, and can assure all prospective students that should they intrust their electrical education to the Institute their needs will be carefully studied and their interests zealously guarded.

In connection with the work of the Institute, mention should not be omitted of the beautiful, artistic and interesting book of information, entitled "Can I Become an Electrical Engineer," which is sent free upon request, and which contains one of the most complete and perfect portrait collections of the prominent scientists and engineers who have succeeded in making the profession of electrical engineering what it is to-day. We cannot too strongly urge anyone at all interested in electricity to apply for this beautiful book at the home offices of the Institute, 120 Liberty street, New York.

[Entered as second-class matter at the New York Post Office, April 3, 1898.]

Vol. XXVI. NEW YORK, JULY 14, 1898. No. 532.

Sault Ste. Marie as an Electrical Centre.

IT has long since been demonstrated that the wealth of modern nations consists largely in the facility and low cost of generating power; in other words, given equal skill and enterprise that nation must have the advantage which is so conditioned that the cost of generating power is lower than that of its competitors. When to this great advantage is added an abundance of the natural resources the final winners in the race of commerce can be readily picked out. It was therefore an object lesson of the most pronounced kind that was enjoyed by those who participated in the recent floating meeting of the Northwestern Electrical Association on the Great Lakes. Everywhere they were brought face to face with the possibilities, indeed the probabilities, that this region is destined to enormous commercial and manufacturing expansion, first owing to the contiguity of raw natural products, and again to the proximity of sources of power to convert these products into marketable shape—the combination of resources as well as the power available being of a magnitude undoubtedly without parallel on the face of the globe. It is as yet too early to predict just where will be located the centre of commerce on the lakes. It goes without saying that the great metropolis of the future will grow up in close proximity to one of the great waterfalls or rapids. Niagara Falls has made a good start; Duluth and West Superior, located at the head of Lake Superior, will some day make available the power of the St. Louis River; Massena, N. Y., on the St. Lawrence, will also be at work electrically on a large scale within a comparatively short time. All these locations have claims to pre-eminence, but it is the claims of another of these favored localities that we deem it appropriate to dwell on more particularly here, and that is Sault Ste. Marie. It is here that Lake Superior, the greatest of the chain of lakes, overflows into its neighbor, Lake Michigan, and though the fall is only twenty feet, yet the enormous volume of the overflow makes available hundreds of thousands of horse power.

What the future has in store for this locality was most lucidly and entertainingly brought out in the address delivered by Mr. F. H. Clergue, of Ste. Marie, who justified the citing of himself as an authority by stating that every prediction he had thus far made regarding the Sault has been realized. The power available at this place being granted, it remained for Mr. Clergue only to show in what manner it is to be utilized, and in this he certainly succeeded in marshalling an array of facts which it would be difficult to controvert. To begin with, it was pointed out that the Sault Ste. Marie locks constituted the threshold to the most important storehouse of national wealth on the face of the globe. The wheat area tributary to Lake Superior, including that in British Columbia, exceeds all of the wheat area in

the world beside, while at the same time the quality of the wheat grown is unsurpassed. Every ounce of that wheat, according to Mr. Clergue, must come through the Sault Canal. But instead of passing by it in the ships' holds it would soon be ground into flour at that point, for nowhere else was power to be had at less cost. He predicted, in fact, that within five years from now the amount of wheat ground at the Sault would reach 25,000 barrels of flour per day.

Turning to the products of the forest, Mr. Clergue pointed to the still unbroken wilderness, the outskirts of which were visible from the Sault, and which stretches northward for a thousand miles to Hudson's Bay, a wilderness of virgin forests containing all sorts of valuable woods, some of which have become almost if not quite exhausted on this side of the border. All this would come to the Sault to be sawed into lumber, or converted into wood pulp, the latter industry having already secured a splendid foothold.

But what will perhaps be of special interest to the electrical fraternity are Mr. Clergue's statements as to the direct applications of the current to the reduction of metals from their ores, to the production of calcium carbide, and to electrolytic purposes. The most strikingly suggestive of the facts brought out is that 20,000 h. p. of electrical energy is to be installed at once to operate electrical furnaces for the production of nickel steel, the entire product having been contracted for by the great German gun and armor making firm of Friedrich Krupp & Co., of Essen. The nickel ore is obtained in Canada at a distance of about 150 miles from the Sault, while the iron in unparalleled purity and abundance is within a distance of 200 miles. The proximity of the ore supply to the source of power and the improved methods adopted for obtaining the alloy have made it possible to sell it at a large profit at the current market prices. As to carbide, the existing works of the Union Carbide Co., at the Sault, will be but a bagatelle compared with those to be created in the near future. We note the giving out this week of an order for twenty 500 h. p. Walker generators to supply the new carbide works to be erected on the American side.

But these are not all of the direct applications of the Sault power to the extraction of wealth from its neighboring localities and their product. We are told indeed that negotiations are now in progress according to which the copper from the Calumet and Hecla mines will be subjected to electrolytic treatment for the extraction of the silver contained in them, 10,000 h. p. of electrical generators being about to be installed for that purpose alone.

If to the facts above enumerated it be added that an iron ship can be built on Lake Superior cheaper than one of wood at Bath, Me., the impetus which this industry will receive in the region under discussion must be apparent. Taking into account only the actual facts and contracts entered into for immediate power utilization at the Sault, that alone would suffice to make the future of any community one of stability. One is forced to the conviction, indeed, that Mr. Clergue, enthusiastic advocate though he be, is not over sanguine and that his prophecies stand an excellent chance of being realized. Certain it is that Sault Ste. Marie is fortunate in having among its workers one so confident of success and withal one so competent as an organizer.

Signs of the Trolley Times.

THE extreme degree of the change from the original opposition to trolley roads is shown in a remarkable manner by the proceedings of a recent large political convention in Vermont, when a resolution was passed inviting the State legislative members to vote "for all bills that tend to establish new electric railroads leading to the now more inaccessible localities so rich in agricultural products, lumber and minerals, passing through scenery unsurpassed in this State, which we believe will tend to the building up and increasing of the material prosperity of the country." This is the right way to regard the new agency, and we could only wish that every political convention were as intelligent and liberal in its attitude toward new enterprises and the corporations pushing such necessary schemes forward. We doubt if a single instance can be pointed to in which the rural trolley has been other than a distinct boon and benefit anywhere in the United States.

The application of the trolley to these rural and back regions has, in truth, become one of the great social and technical ques-

tions. We are interested to note that at the recent meeting of the Canadian Electrical Association serious attention was drawn to a plan for the standardization of farm wagons in such a way that they could be taken aboard bodily by trolley trucks and thus hauled to and from market. At first blush, this looks like a rather wild project, but we confess we can see no good reason why some such plan should not be carried out in every rural region now tapped by a trolley service. The lessening of the cost for haulage and of loss from spoilage of produce would be enormous; the trolley would open up new country and a new source of income; the rates would be so low as to encourage the development of new lines of cultivation, and the ties between town and country would be closer knit than ever. These things will come, and must come soon, with electricity as the prime factor in their coming.

Progress in Electro-Metallurgy.

THE rate of development in the field of electro-metallurgy is not fully appreciated by the public, and Mr. Andreoli has done well to summarize it recently in a review of the work done during the past year. Much of the survey is, of course, familiar, but there are many features of novel or special interest. The electro-metallurgy of lead finds its champion in Dr. Tommasi, who has succeeded admirably in the desilverizing of lead, a process which can be advantageously applied to the treatment of poor lead ores. We all know of the enormous development of the electrolytic refining of copper in the United States, which has no parallel in the world; and the refining of metal by a similar process at the expense of only one electrical horse power per hour for the refinement of one pound of metal. One of the greatest steps forward in the electrolytic production of chlorine and caustic soda has been made by the Castner-Kellner Alkali Company, who are erecting large works both in this country and England, and the Parent Electrolytic Company, which owns the new Hargreaves-Bird process, and is starting an important installation for the manufacture of bleaching powder and chlorates. Of the Haycraft process of gold reduction only good reports have reached us, while by means of the Cassel process, gold has been successfully extracted from telluride ores. The enormous production of aluminum during the past year has been unprecedented and is largely due to improvements and cheapening of the methods employed for its production. Still fresh in our minds is the remarkable success achieved by Mr. Cowper-Coles in the electro-deposition of zinc on a commercial scale and his method for making parabolic mirrors. A distinct advance has been made in electro-metallurgy by the employment of electrolytic precipitation. This process is governed by an entirely different set of laws from those governing the electro-deposition of metals, and it has already been successfully employed in the precipitation of gold, according to Mr. Andreoli, in the *Engineering and Mining Journal*.

So much for the past. A glimpse into the future reveals great possibilities for the employment of both the alternating and high tension currents for electro-chemical purposes. Sir William Crookes has already employed alternating currents for the treatment of auriferous ores, others have followed in new directions and already numerous experiments are being made to test the availability of high tension currents for electro-deposition.

Brayton—Wait.

Mr. William S. Brayton, of the New York office of the General Electric Company was married May 3 last to Miss Alice Wait, of Ithaca. Mr. Brayton is a graduate of Cornell, and passed through the works at Schenectady before assuming his duties at the New York office. He is a favorite among all his associates, who testified their appreciation by presenting him with a handsome souvenir of their esteem. We offer our congratulations to the happy couple.

American Institute of Electrical Engineers.

At the meeting of the Executive Committee, June 24, Mr. C. O. Mailloux was elected a vice-president of the Institute to fill the vacancy caused by the recent election of Dr. A. E. Kennelly to the presidency. Mr. Robert N. Baylis was also appointed a member of the Board of Examiners, succeeding the late Dr. Chas. E. Emery.

The following associate members were elected: Walter Cummings Allen, Inspector of Electric Lighting, Government of District of Columbia, District Building, Washington, D. C.; Albert H. Armstrong, Electrical Engineer, General Electric Co., Schenectady, N. Y.; Geo. A. Damon, with B. J. Arnold, Electrical Engineer, 1541 Marquette Building, Chicago, Ill.; Frank H. Dexter, student Cornell University, residence, 51 Huestis street, Ithaca, N. Y.; P. M. Downing, Supt. Electrical Dept. Blue Lakes Water Co., Blue Lakes City via Jackson, Cal.; Joseph Lyons, Patent Solicitor, with Gustav Bissing, 908 G. street, Washington, D. C.

The following associate members were transferred to membership: Alfred A. Thresher, Electrical Engineer and Proprietor, Thresher Electric Co., Dayton, O.; William B. Jackson, New York and Staten Island Electric Co., West New Brighton, N. Y.; Paul M. Lincoln, Electrical Superintendent Cataract Construction Co., Niagara Falls, N. Y.; Thorburn Reid, Consulting Electrical Engineer, 120 Liberty street, New York City; Philip Green Gossler, Electrical Engineer, Royal Electric Co., Montreal, P. Q.; Theodore E. Theberath, Pacific Coast Engineer, Stanley Electric Co., San Francisco, Cal.; Frederick M. Pedersen, Assistant Electrical Engineer, Crocker-Wheeler Electric Co., New York City; Will K. Dunlap, Electrical Engineer, Westinghouse E. and M. Co., Niagara Falls, N. Y.

Eighth Annual Meeting, Canadian Electrical Association.

A very successful meeting has just been concluded at the Windsor Hotel, Montreal, by the Canadian Electrical Association, being the eighth annual convention of that body. The meeting was conducted by President Yule, of Guelph, Ont., who delivered an excellent inaugural address. Papers were read by Mr. A. A. Wright on "How to Overcome Some of the Difficulties Encountered by Central Station Men;" L. W. D. Magie on "The Electrical Utilization of Water Power;" W. T. Bonner on "Goods Traffic on Suburban Trolley Roads." Visits were paid to the Lachine Hydraulic Works, the Bell telephone exchange, the Montreal street railway system, etc. The convention closed with a banquet at the Windsor, when speeches were made by members and guests, about 150 being present.

New York Electrical Society.

The following members of the New York Electrical Society who have changed their residence are requested to send their new address to the secretary, No. 120 Liberty street, New York City: B. F. Sherman, R. S. Dobbie, D. D. Book, H. Van Sands, Fred Reed, C. W. Raymond, W. F. Collins, C. E. Hart, J. Egan, G. C. Webb, D. H. Washburn, J. C. Harris, W. Schwein, A. S. Miskin, J. W. McLogan, Meno Fedden, W. A. Giles, Thomas Bennett, T. A. Fowler, S. J. Harris, C. E. Chinnock, R. Crawford, A. C. Greenberg, B. F. Card, A. B. Bennett, N. Hall, J. D. Underhill, J. A. Cabot, W. E. Lamb, E. Denning, R. A. Mitchell, R. Leichman, H. A. Dingle, C. Herman, Leo Bock, Jr., H. F. Salamons, A. G. Holcombe, L. J. O'Reilly, A. V. Waldron, Harry Cette, C. A. Thompson, E. E. Stark, J. T. Palmer, T. F. Grover, J. C. Henry, J. W. Doyle, R. Varley, C. H. Wright, C. C. Gartland, John Deane, Jr., F. E. Dolbier, C. A. G. Groenbeck, James Stewart, C. F. Green, M. W. Grovesteen, G. Arnold, J. S. Cobb, D. H. Starralt, E. Voelckel, G. R. Shepard, W. L. Tamblyn, A. Stamm, C. J. Bickley, H. B. Niles, J. McMahon, E. S. Reid, J. H. Longstreet, M. B. Meddler, C. P. Gott, A. C. Barrett, A. W. Steiger, E. C. Miller, A. McKinnon.

Alternating Current Transformers—From the Station Manager's Viewpoint.¹—I.

BY W. F. WHITE.

IN the early days of alternating central station development, many a sale of alternating central station equipment was lost to direct current competitors by the facts, figures and fancies which the salesmen of direct current apparatus were able to advance concerning the wastefulness of energy, the expense of maintenance, and the danger to life which purchasers must accept as inseparably wedded to any transformer system.

Notwithstanding that the danger to life was unfortunately made much of, and the facts grossly misrepresented, still the correctness of many of these arguments, in the light of present knowledge, stands up remarkably well under the scrutiny of qualitative analysis. And it is even more remarkable, in view of the natural tendency to exaggerate, induced by zeal to make sales, how little, if any, were the facts as to these evils overdrawn or magnified. Quantitative analysis, in fact, proves that most figures then given to show the amount of transformer "leakages" were understated. On the part of salesmen this was undoubtedly more a mistake of the head than of the heart, for while some few of them knew the results of some isolated tests of some particular size of one type or manufacture of transformer, no one, whether salesman, engineer and designer, or manufacturer, had any knowledge or conception of the cumulative effect of transformer losses on the station output. Such little knowledge as had then been acquired related more to the transformer efficiency under certain percentages of rated load, than to all day efficiency, or the twenty-four hour ratio of energy output to energy absorbed under average conditions.

Little, if anything, was known of transformer core losses, and the effect of power factor on station and line capacities had not had consideration. As long ago as 1892 the writer, in making a careful examination into the operations of one of the then largest alternating stations in this country, made the discovery that with a net meter rate to consumers of about twenty (20) cents per 1,000 watt hours, the income per k. w. hour output at the switchboard was only about six cents, showing an average loss from station switchboard to consumer's meter of about seventy per cent.

Current was supplied in accordance with the then existing universal practice, through one or more transformers for each customer. In two or three cases, for large installations, as many as eighteen or twenty transformers were erected for a single customer, no transformer of more than 75 lights capacity being used, the transformer primaries being connected in multiple, but the secondaries feeding entirely distinct and separate circuits.

Of each 1,000 watt hours output at the switchboard, it was estimated that approximately 300 watt-hours were delivered through the customers' secondary meters, 600 watt-hours were accounted for by transformer core losses, leaving 100 watt-hours to be accounted for by transmission and other losses.

A statement of these conclusions to a well known manufacturer who had supplied the wattmeters and many of the transformers, elicited the opinion that either the primary meters registered too fast or the secondary meters too slow.

A meter expert from the factory accordingly spent several weeks in testing all primary and secondary meters, found them correct and proved that the apparent discrepancy was not due to the meter end of the plant equipment. With the writer's recommendation that a three-wire secondary network be erected, using 100-volt lamps, and fed through large transformers at frequent centres of distribution, the matter was dropped; but there is no doubt that the proportion of the output attributed to transformer losses was approximately correct.

Since that time it has been the writer's good fortune to be in touch with a considerable number of alternating plants, giving him knowledge of their operating results, and he does not hesi-

tate to assert that very few plants exist giving continuous service, using separate transformers for individual customers, and charging from twelve cents to twenty cents per 1,000 watt hours, secondary meter measurement, whose income per k. w. hour output at the switchboard exceeds from four cents to seven cents. In other words, the ordinary transmission, transforming and distribution losses are commonly as much as 200 per cent. of the customers' demands, as shown by the customers' meters. This does not mean operating expenses three times as great as if all these losses were eliminated, but it does mean that large expenditures are made for fuel and feed water for the keeping warm of numerous transformers operating about twenty hours per day with open secondaries. And great numbers of small transformers also mean great variations of secondary voltage, large bills for lamp renewals, unsatisfactory service, and a reduced number of lamps which can be served at any instant from a given generator capacity. To show the benefits to be derived by using a secondary network, fed by large transformers working in multiple, but located one at each feeding point or local centre of distribution, as compared with the use of small transformers, one or more to a customer, the writer presents some results accomplished by an existing plant in remodeling its transformer system in accordance with these ideas.

Jan. 1, 1895, this plant was serving 16,702 incandescent lamps (16 c. p. equivalent) through 547 transformers of 22,190 lamps rated capacity, each transformer averaging 40.6 lamps capacity and serving 30.6 lamps. The transformer load, with open secondaries, was, as near as could be determined, about 80 amperes, at 1,000 volts. In view of the fact that the maximum load never exceeded fifty per cent. of the lamps' capacity connected, it was evident that a very considerable reduction could be made both in the number of transformers connected and in their aggregate capacity, by the use of a secondary network. The theoretical limit was to reduce the transformer capacity to equal the maximum load, which would lower the capacity connected from 22,190 lamps to about 8,000 lamps, a reduction of about 64 per cent. This limit was evidently impossible of attainment, because of the large number of isolated installations, especially in the residence districts, requiring individual transformers which of necessity must generally be of capacity equal to several times the average load. A system of three-wire secondary networks was laid out, and estimates made showing a possible reduction of almost 80 per cent. in the number, and of about 50 per cent. in the lamps' capacity of transformers connected. A large number of tests of core losses of all sizes of transformers in service was then made, for estimating the total core losses for the plant and for comparisons with the estimated core losses of the large transformers to be erected in replacing the old.

An illustration of one or two of these comparisons may be of interest. One installation of approximately 700 lamps was fed through a large bank of small transformers having an aggregate core loss of 4,440 watts, which could be replaced by two transformers having a combined estimated core loss of 310 watts. On the basis of the number of watt hours per pound of coal then being produced by the plant, not taking into account any line losses, this example shows the following results:

	Tons coal.
4,440 watts—38,894,400 watthours per year require.....	190.6
310 watts—2,715,600 watthours per year require.....	8.4

Annual saving, 36,178,800 watt-hours per year require.....182.2

The annual income from this installation was about \$2,100.00, at 12 cents per 1,000 watt-hours. With a secondary output of about 17,800,000 watt hours, and transformer core losses of about 36,894,400 watt hours, the income per k. w. hour output at the switchboard for this installation was very evidently less than 0.04, and the core losses were more than double the total secondary output.

CHILI. A company has been formed at Berlin, under the title of the Electric Power Company of Santiago de Chili, with a capital of 24,000,000 marks, of which Wernher, Beit & Co., of Berlin, take 12,000,000 marks, while the balance is taken in equal proportion by the Société Générale d'Electricité. Part of the capital will be offered for subscription in England. Extensive electrical undertakings in Chili are soon to be started by the company.

¹Paper read at the General Meeting of the A. I. E. E., Omaha, June, 1898.

Silver Plating Plant at the Hotel Metropole, New York.

OWING to the hard usage to which the silverware in a modern hotel is put, and the large number of silver-plated articles in use at such a place, the management of the Hotel Metropole, at Forty-second street and Broadway, New York, saw fit some time ago to install their own silver-plating plant to renovate all articles from which the silver had been worn off. The plant, which has been in operation for some time, has fully justified the first cost of the outfit, and has shown the economy and feasibility of this novel scheme. The United Electric L. & P. Company, which supplies current to the hotel, leads its high potential circuit into the sub-cellar, where it is transformed to 220 volts by means of two 1,000-light converters. In close proximity to this place the hotel management has installed the silver-plating plant, which consists of the following apparatus: A 2 h. p. 200-volt 2-phase Tesla motor running at 1,800 revolutions per minute, belted by means of a countershaft to a buffer running at 3,000 revolutions per minute, and a plating dynamo delivering 75 amperes at a pressure of 5 volts; the necessary fuses, an overload circuit breaker and the conductors, which in this case are hollow copper tubes, leading to the various vats. There are in all four of these vats, each holding 25 gallons of liquid. They are the nickel, copper, silver and striking solutions, the use of which will be explained later. The writer witnessed the plating of an old soup ladle which had been discarded some time ago on ac-

credit is due for this novel installation, states that the management has effected a considerable saving in silver-plating expenses since this plant has been installed. Mr. Max Wahl is chief engineer of the hotel and Mr. D. Valintini, an experienced silver-plater, is employed as operator. There is obviously an illimitable field for the extension of such work.

Prof. Andrew Jamieson's Suggestions Regarding the Conventional Electrical Diagrams.

IN our issue of February 24, 1898, we published in the form of a double data sheet the conventional electrical diagrams embodied in the report of a special committee of the Chicago Electrical Association. These diagrams, which were submitted for the consideration of electrical engineers in this country and abroad, have met with considerable favor and will no doubt bring about finally the much desired uniformity of electrical diagrams. We are, therefore, pleased to note the suggestions offered by the eminent English authority, Prof. Andrew Jamieson, which we publish below together with an abstract of a letter to the London Electrical Review, accompanying the diagrams. After complimenting the Chicago Electrical Association on their energy and ability in going one step further than any other similar association has ever done, Professor Jamieson continues as follows:

In the first place, their figures for series, shunt and compound wound dynamos or motors, have the objections of rep-

CONVENTIONAL ELECTRICAL DIAGRAMS.

count of its utter uselessness as a piece of ornamental tableware. To better understand the operation of silver-plating this ladle, let us follow each step as though we were watching the process. At first, the article is buffed until it appears clean and free from oxides or dirt. It is then dipped repeatedly in hot triple X lye in order to remove all traces of grease, after which it is washed off in water. It is then placed in a copper bath where it receives a very thin but complete coating of copper. It is now taken to the buffer again and given a high polish, stale beer being used during this operation, after which it receives a thin preliminary coating of silver in the striking solution which prepares it for its final coating of silver. The duration of each process is left entirely to the trained judgment of the operator, who can judge the thickness of the deposit by the action of his electrolyte and the amount of bubbles given off at the electrodes. After the article has been thus plated, it is dried off by being placed in sawdust, and is then finally given its exquisite polish by means of the buffer.

The entire operation, which has lasted less than twenty minutes, makes the article as good as new at a very small expense of energy. The small plant installed here is said to be of sufficient size to handle all the plating of four hotels of this size, only one or perhaps two operators being required to handle this output. As the operator at this hotel is not kept busy constantly, the guests not eating the silver off with sufficient rapidity, he devotes the remainder of his time to the buffing of the silverware. Mr. J. M. Lux, the treasurer of the hotel, to whom much

resenting the field coils by zig-zag lines which have hitherto been universally adopted to represent non-inductive resistances, whereas the field coils of such dynamos are anything but non-inductive. Further, in the case of the series and compound wound dynamos or motors, their diagrams are unnecessarily complicated by drawing the leads from each brush with two right angles, whereas in the diagrams usually adopted by electricians, and shown in my figures to the left, the leads come straight away from the brushes.

Their figure for a motor generator is greatly simplified, and conveys the full meaning desired to be imparted by that which I have shown on the left.

With regard to the storage cell, I think all that is necessary to distinguish it from a primary battery are the letters S and B respectively, placed underneath the usually accepted sign of long thin and short thick parallel lines.

Granted that there are cases where it might be necessary to distinguish between the hand generators at subscribers' stations and the power generators at a central office, I don't see the slightest necessity of complicating the figure of a constantly driven magneto by inserting lines to represent the belt when a mere arrow on the armature spindle would be sufficient, as shown by my figure to the left of theirs.

With regard to ammeters, voltmeters, wattmeters and polarity indicators, or galvanometers, I think you will agree with me that those shown on the left are much simpler, neater, and sufficiently distinguished from each other by the letters A, V, W and G.

In the representations of an inductive resistance and a solenoid, it will be noticed that the iron core is omitted in my suggestion as shown on the left. Surely, the fact of a wire being coiled in a spiral form is sufficient to convey the idea of the presence of a certain amount of self-induction?

With respect to the next diagram, we do not in this country speak or write of a connection to the "ground," but to the earth, and what could be more in harmony with the well known and long accepted telegraph symbol as shown on the left?

There can be no objection to a number of crosses, as shown, to represent arc lamps in series, but for the indication of a single lamp I should recommend the diagram on the left.

My next three diagrams, as representing an incandescent lamp, a fuse, and a telegraph key, are also more in conformity with practice than the corresponding ones indicated by the Chicago Association.

Finally, we have again to find fault with their use of the well known symbol for non-inductive resistances in the representation of a transformer.

Other objections might have been found, but these are sufficient to show a diversity between American, British and Continental practice, and hence the need for coming to an early state of uniformity.

The Fessenden X-Ray Apparatus.

AN improved and convenient R-ray apparatus, and one which has met with considerable favor among medical men and in hospitals, has recently been placed on the market by the Fessenden Manufacturing Company, 136 South Beatty street, Pittsburg, Pa. The machine, which is illustrated below, is designed for use with any direct current, either that from storage battery, primary battery or from a 110, 220 or 500-volt circuit, and by the use of a rotary transformer, which the company also manufactures, an alternating current can be used. The apparatus is mounted in portable square cabinets, those for a 6-inch spark, as illustrated, being about 18 inches square at the base and 3 feet in height, tapering slightly to the top. It is provided with a jointed or flexible wooden arm for holding the tube and connections, which has a range of about 4 feet, so that the tube can be adjusted in any position. The resistance coils are contained in a porcelain plate, mounted on one side of the cabinet and protected with a perforated brass cover. The interior mechanism consists of primary and secondary coils. The primary coil and core are encased in a hard rubber tube, which is about three inches in diameter, which is placed in a vertical position at the axis of the cabinet, and extends from the bottom to the top. The core is made up of very fine soft iron wire, insulated by shellac, and about this is the primary winding. The secondary coils are wound in three sections in the form of a disc or pulley about 12 inches in diameter, with a 3-inch face. These coils embrace the vertical tube and are about 2 inches apart, and have the appearance of three pulleys on a vertical shaft. This arrangement prevents the possibility of the secondary coils becoming overheated, or the insulation breaking down, and the manufacturers claim that not one of their coils has ever failed from any cause. On the top of the cabinet is a small 6-inch square case, which contains a small motor, that is placed with its armature directly over the magnet core, and runs in oil. This motor consists of a small wheel 4 inches in diameter, with a 1-inch face, which is made of brass, and has iron armature pieces set in. It has a 4-section commutator about $\frac{3}{8}$ of an inch from the face of the wheel on one side; the brush consists of a flat metal conductor, which presses against the contact segments. As the pulley revolves, being actuated by the magnetism of the core, the primary current is broken or divided, thus setting up induced currents in the secondary, which reach a very high potential, enabling a spark to pass from 6 to 12 inches in length. Handles are provided, as shown, for regulating the spark gaps. One of the gaps regulates the volume of the current through the tube, another the vacuum of the tube,

and the third is a safety gap, to prevent the injuring of the tube or machine. The construction of the machine is very simple, and it can be operated by a novice from the printed instructions. With the machines are provided fluoroscopes and tubes specially made after the company's specifications. In the tube the vacuum is regulated automatically. Specially prepared plates for radiograph work are also provided, together with a developing liquid. Photographs made with these machines are unusually clear, and

IMPROVED FESSENDEN X-RAY OUTFIT.

only a short exposure is required, depending, of course, upon the portion of the body which it is designed to picture, a 4-second exposure being sufficient for photographing the bones of the hand, while for one through the pelvis only four minutes are required.

Reminiscences and a Glimpse into the Future.¹

BY PROF. ELISHA GRAY.

AFTER thanking the members of the Association for the courtesies they had extended to him by inviting him to be their guest on the trip and assuring them of the pleasure he had derived from it, Professor Gray made the following interesting remarks:

When I began my career as a so-called electrician there was no science of electricity. We knew nothing about ohms, amperes or volts, or any of those other peculiar terms which have grown up as the science has progressed. We had to do our experimenting just about as our mothers used to make cake. You know they did not have cook books in those days, and they put about enough of this and that and the other together and made cake. Sometimes it came out good and sometimes it did not. If it failed, they did not know why it failed, and if it was

¹Abstract of remarks made by Prof. Gray at the convention of the N. W. Elec. Assoc., Duluth, June, 1898.

a success they did not exactly know why that was either. That is about the way we had to conduct our experiments. We knew nothing about the relations of wires to magnets, resistance, etc. I remember when the first rheostat came into this country. It was a Varley rheostat with a differential galvanometer, and Charles H. Summers, of Chicago, electrician of the Western Union, had the first one. He used to carry it under his arm, and he was a great man. That was the beginning of ohms in this country—the beginning of the measurement of resistances. I have seen telegraph joints cut out that gave a measured resistance of 35,000 ohms, and yet they worked through those resistances in those days, but it did not dare to mist or rain the least bit, or the current was gone. We did not know then what was the matter with us.

I did not begin quite so far back as a certain professor of physics in my alma mater in its very early days, before the time of the telegraph, or at least before it amounted to anything—I do not think he had ever heard of it, but he was taking his class through a course of "electricity." It took him an hour one day. He showed the experiments of the frictional electrical machine, and talked to them about Franklin's having caught the forked lightning from the clouds, tamed it, and made it subservient to the will of man. You know how it goes, a regular Fourth of July speech, and then he said: "Young men, you were born too late to witness the development of this great science, electricity." I often wonder whether if the good professor is allowed to look down from his far-off home and see the progress that electricity has been making since his time, he does not often think of that little speech he made to the boys over fifty years ago on the subject of electricity. I think I should, under the same circumstances.

We had no electric lights in those days, we had no electric railroads, we did not do our cooking by electricity, we did not ride on the cars by electricity—those things were not thought of—we did not talk from town to town by electricity. I will quote a little poem as apropos of this subject, entitled the "Difference Between the Now and the Then."

"In the olden time, along the street,
A glimmering lantern led the feet,
When on a midnight stroll;
But now we catch, when night is night,
A piece of lightning from the sky
And stick it on a pole.

Time was when one must hold his ear
Close to the whispering voice to hear,
Like deaf men, nigh and nigher;
But now, from town to town he talks,
And puts his nose into a box,
And whispers through a wire.

In other days we took a car
Drawn by a horse, if going far,
And felt that we were blest.
But now the conductor takes the fare
And sticks a broomstick in the air—
The lightning does the rest."

Gentlemen, as I said before, I congratulate you that you live in this age. I congratulate you that you can begin where you are beginning in this science of electricity. We are apt to speak of it as just on the threshold or just in its infancy. Well, it is a pretty healthy infant; yet who is bold enough to say that it is not yet comparatively in its infancy? I do not know what the outcome is to be, but I am sure we have not reached the end by a long, long way. I expect—no, I do not know that I expect to see it—but I think some of you may see it, and if you do not, some of your children will, see the time when we will have done away with the steam engine, when we will take the energy which is stored in the wood and the coal, directly as electricity, without having to put it through the steam engine and the dynamo, for the various uses to which it can be put. I say, I think that that time is coming. It may not be reached in our lifetime, but it seems to me legitimate that we may look forward to that. We will have no use for it. We will remember steam very affectionately for what it has been in the world, and what it is to us now, but there will be no necessity for its use then.

MR. H. G. ISSERTEL, E. E., has taken the management of the New England office of the Walker Company and will have his headquarters at room 313, 53 State street, Boston, Mass., where he will be glad to welcome old friends and new orders. He is a former New Englander, in the electrical sense, having been one of the corps of experts of the old Thomson-Houston Company, and having assisted in the construction of such roads as the Boston West End, the Lynn & Boston, etc.

LIEUTENANT WOOD, of the Ball & Wood Engine Company, New York City, was prominent in the great fight in which Cervera's fleet was smashed, and as an officer of the saucy yacht "Corsair," now the "Gloucester," had no small share in the glory of "doing up" the two torpedo boat destroyers at the same moment. Lieutenant Wood's name was mentioned in many of the newspaper dispatches, and his associate, Mr. C. R. Vincent, has now had the pleasure of getting a cable message from him, via Jamaica, stating the news of the glorious victory and saying that he is well and ready for another.

The Skinner Automatic Engine and Improved Lubricating System.

The Skinner engine has attracted the attention of engineers on account of its close governing qualities and efficient system of lubrication. The engine, which is shown in perspective in Fig. 1 has attached to it a governor, built on Shepherd's patent, which consists of but three operating parts mounted in the wheel, and is probably the only type of governor which will respond to sudden change of load without racing, in which friction is entirely eliminated. According to reliable tests made with this governor, the same speed was maintained with steam at 30 pounds and 125 pounds, and the speed was changed 30 per cent. by simply adding to or taking from the weights, requiring no other adjustment of the governor. The manufacturers guarantee this governor to regulate within one-half of one per cent.

The most remarkable feature of this engine, however, is its novel system of lubrication, shown in Fig. 2. This system does not necessitate the taking away of the oil for filtration, and it is

FIG. 1.—SKINNER AUTOMATIC ENGINE.

claimed that the attendant need not touch the lubricating apparatus from one year's end to the other.

The new features in this system are: Adjustable oil feeders, through which oil is conveyed to sight-feed glasses, and which can be swung away from the glasses when access to the interior of the engine is desired. A noiseless pump with a positive motion valve. An oil and water separator, absolutely preventing water from reaching the supply tank. An oil purifier in connection with the supply tank. All pipes and connections outside of the bed in full view and reach of the attendant. Not a strainer nor any filtering material, such as waste or sponge, to obstruct free circulation of oil through the entire system. The feed is in plain sight of the attendant.

After passing through the engine, the oil is separated from

the water that naturally follows it, is conducted to a filter which cleans it, and when it again enters the engine it is just as pure as when first introduced.

These features are entirely new and novel, patents for which are now pending. The manner in which it is attached to the engine is such as to enable the operator at all times to have ready access to any part of the engine for adjustment or examination, and by loosening three screws the entire feeding mechanism can be removed from the engine.

Referring to Fig. 2, which shows very plainly the details of the system, the guides, cross-head and cross-head pin are oiled by a jointed tube overhanging the guides, the oil reaching the guides and dropping through the sight-feed glass in each guide, the feed being regulated by feed screws for each glass. The feed tube is hinged to the bracket bolted to the top of the bed. No adjustment of screws is necessary to stop the feed. Raising the tube to the vertical position, shown by the dotted lines, shuts off the oil. When the feeder is in this position, ready access to the cross-head and connecting rod for adjustment is afforded. Both the main bearings are oiled by an arc tube, which also supplies the oil necessary for proper lubrication of the crank, through the same glasses that oil the bearings. The feeder is hinged to brackets bolted to the top of bed, and when an examination of the crank is desired, the feeder can be thrown back from the crank, as shown by the dotted lines. When in this position the oil supply is shut off. These jointed feeders can be entirely removed from the bed by loosening a screw at each joint. Oil is furnished to the feeders from a reservoir located above the bed, shown in Fig. 2. The oil is forced to this reservoir by means of a pump attached to the valve slide. The capacity of this pump is greatly in excess of that required to oil the engine, keeping the reservoir full of oil at all times, any oil in excess of the wants of the engine being returned to the supply tank by means of a pipe, provided to take care of this overflow. This pump has a positive motion

FIG. 2.—SHOWING LUBRICATING SYSTEM OF SKINNER AUTOMATIC ENGINE.

valve similar to a piston valve in an engine. It is perfectly noiseless and not liable to become obstructed. The valve seat and valve can be removed from the pump and when removed the oil is prevented from escaping from the pump and is carried to the feeders from the reservoir the same as though the pump were working. The valve can be cleaned and replaced in the pump, when it immediately starts to work again, and it is not necessary to stop the engine nor is the oil feed interrupted.

When the oil leaves the engine it is more or less mixed with water that comes from the piston and valve rods. This enters a receptacle at the end of the bed, which is an oil and water separator. This is an entirely new thing in mechanics. Water and oil flow into this separator, as fast as it comes from the engine, and every particle of oil will be separated from the water and conveyed by means of a pipe back to the supply tank. part of this supply tank being a filter, and the oil is cleansed from all impurities, entering the supply tank proper in as good condition as it was when originally put into the engine. A constant stream of oil is fed to every part of this engine, and the manufacturers state that they guarantee that not a particle of oil will reach the foundation or room that it is placed in.

From tests made the builders guarantee that an engine of 50 h. p. capacity can be operated ten hours per day for one year on a consumption of but five gallons of oil; that at no time will the oil in use show more than $\frac{1}{4}$ per cent. more friction than sample from barrel, and that the system will require no attention from the attendant other than renewing the oil from time to time. The only loss, therefore, is from actual wear.

The engine is manufactured by the Skinner Engine Company, of Erie, Pa.

Purification of Boiler Water.¹

ONE of the most universal causes of inefficiency in small power plants is scale on the inside of boiler flues. This causes not only a loss of fuel by reason of poor conductivity for heat, but also abnormally heats the boiler plates and flues, and causes them to expand to such an extent that leaks of the boiler will be the eventual result. Even explosions may be caused by the sudden breaking away of the scale and admitting the water to highly heated plates, suddenly contracting them. and in so doing, breaking off more scale, and at the same time generating an abnormal amount of steam.

In a power plant that we have erected recently, we have attacked this problem in a different way from that common in this country, although the method is used to some extent in England and Germany.

In order to get a pure water for the boiler, we constructed two tanks 46 and 6 feet deep. They are filled with water from the hot well of the jet condenser, and at the same time a small amount of whitewash is added to the water. The exact amount can be determined by a very simple chemical test. If a little of the water is taken in a tumbler and a few drops of a weak solution of silver nitrate is added, it will give a red precipitate if a sufficient amount of lime has been added. Care should be taken not to add a great excess of lime, although a very small excess will do no harm. After allowing it to stand for about half an hour, a solution of soda ash is added, and then if the water is at all muddy, a very little alum is added. This, however, is not necessary except with quite muddy water. Within an hour the water will begin to turn a greenish-blue, and within two or three hours it may be drawn from the top if necessary, although we prefer to give it 12 to 15 hours to settle in if possible. But even in case we are not able to give it any time at all to settle, we have the water under conditions as favorable as can be obtained by the use of any compound directly in the boiler. Where time is given for the water to settle, all the impurities are in the bottom of the cistern, instead of in the boiler, or, at least, 95 per cent. of them, and a perfectly clean boiler results. The whitewash is added to precipitate all the soluble bicarbonate of lime in the form of the normal carbonate, which is almost absolutely insoluble. The soda ash is added to precipitate the sulphate of lime and the excess of the whitewash.

The water that we operate on contains almost no sulphates, and at first we added only the whitewash, but we found although the boiler scaled but very little the scale that was formed was very tenacious. However, after adding soda ash to remove the excess of lime, we found no scale at all was formed on the flues, and the very small amount of precipitate that found its way to the boiler never caked, but remained as a very flocculent mud until blown off.

A Chimney That Had Outlived Its Usefulness.

WHEN the tracks of the N. Y., N. H. & H. R. R. were recently elevated at Jamaica Plain, Mass., it became necessary to remove a number of the adjacent buildings of the B. F. Sturtevant Co. and to change the location of the existing boiler plant. The chimney, which had previously served as a means of producing draft, was thus rendered absolutely useless because of its distance from the new location of the boilers. It therefore became a question whether another chimney should be erected or a fan employed to produce the draft. Naturally the latter method was adopted, for the B. F. Sturtevant Co. are large manufacturers of fans and are installing

¹Abstract of paper read by Mr. Dow, of Midland, Mich., before the N. W. Elec. Assoc., June, 1898.

large numbers for the purpose of mechanical draft. Accordingly, a specially designed fan was placed on top of the boilers, connection was made to the uptake, and a short stack was provided extending just through the roof. The general arrangement of the apparatus is shown in the accompanying illustration. The fan is equipped with a direct connected upright engine, the speed of which is so regulated by an automatic device that the draft is materially increased when the steam pressure

STURTEVANT MECHANICAL DRAFT FAN OUTFIT ATTACHED TO BOILERS.

falls slightly. The result is practically constant steam pressure. The arrangement has required no attention, fulfils the requirements, makes possible the burning of cheaper fuel, and has a marked influence in the prevention of smoke.

The deterioration of the unused chimney and the utilization of its bricks in the erection of a new building has led to the recent removal of the old means of draft-production, and the passer-by is now favored with the unusual spectacle of a large manufacturing establishment without a chimney, or at least anything that appears to be comprehended by the ordinary defini-

pose. Inasmuch as it is usually built of steel plate, its construction may be such as to most perfectly fulfil the requirements, for it may be used either for forcing the air to the ash-pits or exhausting it from the uptake; it may be placed above the boilers or in any location where the space is not valuable; its capacity may be varied at will; great intensity of draft may be maintained without reference to the conditions of the weather, which so often affect the working of a chimney; the draft may be maintained while the waste heat in the gases is utilized by the economizers, and above all it can be installed for far less first cost than a chimney.

The rapidity with which this method of draft production is being adopted certainly warrants the assertion that the time is at hand when such evidence of its use as is indicated by the absence of a chimney will be found on every hand.

Street Railway Receipts in 1896 and 1897.

The valuable and useful standard publication known as Street Railway Journal's Financial Supplement, "American Street Railway Investments," contains in the 1898 edition, just published, an interesting and instructive comparison of the gross receipts for 1896 and 1897 of the principal American street railway properties, 175 in number. It appears that there are no fewer than 26 properties earning \$1,000,000 or more; 19 earning from \$500,000 to \$1,000,000; 46 earning from \$100,000 to \$500,000. The figures for 84 properties earning less than \$100,000 are also included in the comparisons. In the first group, including the principal street railway properties of the country, the gross receipts for 1897 were 2.2 per cent. greater than the receipts for 1896; in the second group, the receipts decreased 0.11 per cent.; in the third group, comprising the 46 properties earning from \$100,000 to \$500,000, the receipts increased as a whole 1.67 per cent.; and with the smaller systems there was but a slight variation in the

A MANUFACTURING ESTABLISHMENT WITHOUT A CHIMNEY.—EQUIPPED WITH STURTEVANT MECHANICAL DRAFT FAN OUTFITS.

tion of such a structure. The accompanying view represents the works as they now appear, the present steel plate stack from the fan being visible on the right about half way down the length of the buildings. That such means should serve as an efficient substitute for the chimney is not evident until one considers the peculiar adaptability of the fan for such a pur-

receipts for the two years. The entire 175 properties which are presented in tabular form in the "Red Book" show an increase in receipts of 1.9 per cent. in 1897, as compared with 1896.

These increases are all much smaller than those shown in 1896 over 1895. In these two years the difference in gross receipts was 7.4 per cent. of the 1895 figures. Although these compari-

sons are for a portion only of the street railways of the country, they seem to indicate that the latter have just about held their own in 1897, but have done little more than this, and have not kept up the rate of increase promised by last year's reports.

This supplement to the Street Railway Journal contains, as usual, a mass of interesting and valuable statistics relating to street railways, together with 24 fine maps of the more important properties. The operating statistics and balance sheets are presented in tabular form, so that the returns for four or five years past can be inspected without the necessity of referring to previous editions of the book. We believe that this is the only publication of this character in which balance sheets from year to year are directly compared, and yet it is undoubtedly true that the financial condition of properties is never completely understood unless the closest inspection of balance sheets be made, for padding or concealment of earnings is usually brought to light only in the balance sheets.

Illumination of the Grand Canal, Omaha Exposition.

IN addition to the pictures we have already published of the Grand Canal at the Omaha Exposition and of the electrical fountain and effects there, we now present an admirable night view of the scene. The notable fact about this illumination is the entire absence of arc lights. The whole effect is obtained by the use of incandescent lamps of 8 and 16 c. p., at 104 volts. The 8 c. p. lamps are used along the outlines of the buildings. The 16 c. p. lamps are employed around the canal and on certain high points. The plant for the Nautilus fountain around the columnar statue of Neptune, as well as for the illumination, is

ILLUMINATION OF THE GRAND CANAL, OMAHA EXPOSITION.

due, as already noted, to Mr. Stieringer, who was wishful of demonstrating what could be done with incandescents alone out of doors on this large scale. The results, in the large volume of light and in the brilliancy and beauty of the scene, more than justify his predictions. The construction work and details have been carried out by Mr. Henry Rustin, the superintendent of electric light and power at the Exposition.

Electric Traction on an Ohio Canal.

Under an act passed by the Ohio Legislature last spring, an experiment with electric traction on canals is to be made on the Miami and Erie Canal by a trolley railroad company. The plan proposed is a novel one. It is to build a standard gauge track on the towpath on which will be run an electric motor, receiving its power by an overhead trolley. The motor designed for this work will be of 100 h. p. and will, its designer expects, easily pull a tow of at least five heavily laden boats, or more tonnage than a 300 h. p. engine can pull on rails. The track will be ballasted to an even surface so as not to interfere

with the drawing of boats by mules. In the event that the experiment succeeds, the reward of the trolley company will be the right to operate a line of boats for a term of years, paying to the State the same tolls as are now paid by mule-drawn boats.

A New Application of Hertzian Waves.

To obviate the use of the usual conductors in burglar alarm systems for safes, vaults, etc., Mr. Clyde Colman, a resident of Chicago, has invented a system employing Hertzian waves. In accordance with this invention the connecting conductors are entirely dispensed with and a transmitter is provided in the protected structure, which is thrown into operation immediately upon any tampering with the protecting barrier, so as to produce a series of vibrations capable of transmission through the intervening medium to actuate a cohering receiver at the alarm station. The receiver closes the local alarm circuit, causing the bell or other means to produce a signal until the attendant stops it by decohering the particles between the electrodes.

Production of Electrical Energy by the Direct Action of the Atmosphere.

This is the claim made by Mr. Henry N. Warren, who describes the following experiment in the Chemical News, Vol. 76, p. 200, to demonstrate the feasibility of his scheme. Plates are prepared of a special porous compressed graphite, and about one-quarter of each plate is rendered active by immersion in platinic oxalate, drying and igniting in an atmosphere of hydrogen. In contact with a solution of ferrous sulphate, the platinum surface induces oxidation of the iron by the oxygen

of the atmosphere. Several of these plates are attached to a circular lead beam, which surrounds a porous diaphragm containing as negative element a rod of amalgamated zinc, the carbons being so arranged as to allow the platinized portion to project above the solution, which consists of strongly acidified ferric sulphate. On completion of the circuit, a powerful current is at once generated, and continues until the complete reduction of the ferric salt has taken place, which naturally terminates the action. On now withdrawing the zinc, the platinum surface condensing the atmospheric oxygen steadily reoxidizes the ferrous salt, and thus renews the action when required.

Engineering Education.

The Society for the Promotion of Engineering Education will hold its fifth meeting in Room 22, of the Walker Building, of the Massachusetts Institute of Technology, Boston, Mass., August 18, 19 and 20, 1898. J. B. Johnson, St. Louis, Mo., president; Albert Kingsbury, Durham, N. H., secretary.

Classified Digest of U. S. Electrical Patents Issued June 28, 1898.

Alarms and Signals:—

ALARM SYSTEM. C. Coleman, Chicago, Ill., 606,405. Filed Sept. 8, 1897. Employs Hertzian waves and thus eliminates the use of conductors.

RAILWAY SIGNALING SYSTEM. C. H. Davis, New York, 606,450. Filed Dec. 29, 1897. A series of signal devices being arranged so that a given device cannot be set to exhibit a safety signal ahead of a train until it shall have exhibited a danger signal as many times as there are succeeding devices interlocked with it in rear of train, and unless the succeeding devices shall previously have been set to exhibit "danger."

Batteries, Secondary:—

SECONDARY VOLTAIC BATTERY. L. Epstein, London, England, 606,528. Filed Dec. 28, 1895. Employs negative plates in which lead oxide is the active material, and positive plates coated with amalgam of mercury and zinc, troughs in which the positive plates rest and in which the mercury is placed, and casings for the negative plates formed of porous, non-conducting material enclosed between walls which surround the lower part of the plate, the walls having perforations except in their lower portions.

Distribution:—

TRANSFORMER BOX AND HANGER. L. Gutmann, Peoria, Ill., 606,208. Filed Nov. 22, 1897. Combines a main body tapering toward the upper end, a tapering rim forming part of the hanger, located in a parallel plane to the main body, and recesses in the main body for retaining devices for fastening.

SYSTEM OF ELECTRICAL DISTRIBUTION. C. F. Scott and B. G. Lamme, Pittsburgh, Pa., 606,589. Filed Jan. 28, 1897. Comprises an alternating current supply circuit, direct current motors, a rotary transformer taking alternating current from the supply circuit and supplying direct current to the motors and means for varying the alternating current electromotive force supplied to the rotary transformer and thereby varying the direct current electromotive force and the speed of the motors.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE. R. S. Dobbie, Jersey City, N. J., 606,407. Filed June 6, 1892. Comprises a dynamo electric machine having two or more pairs of pole-pieces and a switch for rendering the machine bipolar or multipolar at will.

ELECTRIC MOTOR. J. G. Truman, Lemon City, Fla., 606,605. Filed Jan. 10, 1894. Combines a movable armature with a series of connecting bars attached thereto and electromagnets with which the plates are also connected.

Measurement:—

CURRENT INDICATOR. T. W. Varley, New York, 606,369. Filed July 2, 1897. Designed to construct and arrange astatic needles in such a manner as to form an indicator or ammeter for the current passing through a straight conductor.

ALTERNATING CURRENT MOTOR METER. J. A. Mollinger and K. Kurda, Nuremberg, Germany, 606,630. Filed Dec. 27, 1897. Comprises a shunt field consisting of two inductive resistance coils placed in series with the coil of a choking device, the core of the shunt field magnet being constructed of thick sheet iron, cast iron plate, steel plate or solid iron, and the core of the choking device of thin subdivided well isolated sheet iron.

Miscellaneous:—

INSTRUMENT FOR CALKING SHIPS. W. P. Freeman, New York, 606,199. Filed June 22, 1897. Comprises an electric motor, a reciprocating tool holder, a spring acting on the tool holder in one direction, and a Geneva gearing actuating the tool holder intermittently in the opposite direction.

ELECTROMECHANICAL MUSICAL INSTRUMENT. G. H. Davis, New York, 606,279. Filed May 1, 1896. Details of construction.

ELECTRIC IGNITER FOR GAS ENGINES. A. J. Tackle, Oakland, Cal., 606,312. Filed Oct. 5, 1897. Details of construction.

APPARATUS FOR WELDING, BRAZING AND SOLDERING BY ELECTRICITY. A. Hirsch, Berlin, Germany, 606,842. Filed Dec. 21, 1897. Consists in so mounting and operating the electrodes in a tool that they may be adjusted at the required angle and converged, separated, and otherwise manipulated by one hand as to vary the flame as required.

ELECTRICAL SIGN. M. Norden, New York, 606,356. Filed April 12, 1897. An automatic mechanism for electric signs comprising a shaft and heads, means for revolving them, removable letter bars and contact springs carried by the same and circuit connections, a segment bar upon one of the heads and a contact brush and circuit connections.

PORTABLE ELECTRIC DRILL. E. Holmes, London, England, 606,549. Filed Nov. 18, 1897. Details of construction.

Railways and Appliances:—

ELECTROHYDROSTATIC AUTOMATIC CAR BRAKE. J. Buchel and F. McGloin, New Orleans, La., 606,830. Filed May 22, 1897. Comprises an automatic car brake, a closed fluid pressure conduit, a pump for creating a pressure therein, a brake cylinder connected to the conduit, a controlling valve in the conduit, a weight tending to keep the valve closed and an electromagnet for varying the pressure of the weight upon the valve.

Regulation:—

REGULATION OF ROTARY TRANSFORMER DIRECT CURRENT ELECTROMOTIVE FORCE. B. G. Lamme, Pittsburgh, Pa., 606,560. Filed Feb. 10, 1898. Details of system.

Switches, Cut-Outs, Etc.:—

PUSH BUTTON. F. J. List, Chelsea, Mass., 606,562. Filed Nov. 5, 1897. Consists of an escutcheon provided on its inner face with a chamber and a cross bar, forming a contact point, a push button extending through the escutcheon and having its inner end broadened

into a disc, the wire forming the other electrode being coiled around and upon the disc.

Telegraphs:—

PRINTING TELEGRAPH. B. A. Brooks, Brooklyn, N. Y., 606,829. Filed Jan. 20, 1894. A combined transmitter and distributor, comprising a continuously revolving shaft, a set of key levers, a circuit changer and mechanism between the levers and shaft whereby the depression of any key changes the circuit to send an impulse over the line after a predetermined time corresponding to the key.

TELEGRAPH INSTRUMENT. J. L. Cutler, Cincinnati, O., 606,449. Filed Oct. 18, 1897. Sounder. Details of construction.

Telephones:—

TELEPHONE SYSTEM. W. A. Gustafson, Joliet, Ill., 606,285. Filed Aug. 13, 1896. Comprises electric call and sound transmitting and receiving devices so arranged and combined as to be automatic in breaking and making the bell call circuit when the transmitting and receiving devices are brought into service and replaced out of service.

SYSTEM FOR ELECTRICAL COMMUNICATION. A. T. Brown, Syracuse, N. Y., 606,620. Filed April 9, 1896. Party line telephone system.

Classified Digest of U. S. Electrical Patents Issued July 5, 1898.

Alarms and Signals:—

POLICE PATROL SYSTEM. O. W. Hart, Fall River, Mass., 606,865. Filed Aug. 3, 1897. A telephone transmitter consisting of a case, a mouthpiece on the front of the case, a diaphragm at the rear of the case, a plurality of electrodes extending from the diaphragm toward the mouthpiece and provided therewith a rigid support and means of adjustment.

Batteries, Secondary:—

STORAGE OR SECONDARY BATTERY. R. Ashley, Port Republic, N. J., 11,876, reissued. Filed April 9, 1898. An electrode consisting of horizontal, straight and corrugated metal strips alternating with each other and having spacing pieces between the ends soldered to them.

Conductors, Conduits and Insulators:—

INSULATOR. B. Willard, Schenectady, N. Y., 606,830. Filed April 18, 1898. An insulator for an electric conductor, comprising a metal cap having a receptacle which is other than round, with a body of insulating material arranged to fit into the cap and be free to move in and out, but prevented from turning therein, and means for securing the insulator to a support.

Dynamos and Motors:—

METHOD OF AND APPARATUS FOR GENERATING ALTERNATING CURRENTS. M. Hutin & M. Leblanc, Paris, France, 606,761. Filed March 13, 1894. A method of generating alternating electric currents, by causing electrical alternations of the desired frequency, and re-inforcing the same to the desired volume.

ALTERNATING CURRENT DYNAMO. M. Hutin & M. Leblanc, Paris, France, 606,762. Filed April 19, 1896. Similar to above.

ALTERNATING CURRENT DYNAMO. L. Gutmann, Peoria, Ill., 606,863. Filed Dec. 4, 1897. A stationary ironclad armature, combined with field magnet core for the alternator consisting of three solid structures, a shaft for the field magnet core adapted to rotate, and means for temporarily removing the pieces from the shaft.

Electro-Therapeutics:—

ELECTRIC EXTRACTION OF POISONS. J. B. Campbell, Cincinnati, O., 606,887. Filed Oct. 5, 1896. Consists in providing the negative electrode of an electric battery, with interchangeable receivers of animal, vegetable or mineral substance, to extract a poison from the body of a nature or any kind corresponding with or to the negative electrode employed.

Lamps and Apparatuses:—

SWITCH FOR ARC LAMPS. C. A. Pfuger, Chicago, Ill., 606,939. Filed Dec. 21, 1896. Four terminal switch. Details of construction.

Measurements:—

ELECTRIC METER. W. Stanley, Pittsfield, Mass., and F. Darlington, Great Barrington, Mass., 606,795. Filed Jan. 13, 1898. Comprises a magnetic brake consisting of a rotating disc mounted upon the shaft to be retarded and a permanent magnetic system having a permanent magnet provided with a soft iron pole piece and adjustable projections engaging with the soft iron pole piece.

Miscellaneous:—

ELECTRIC RADIATOR. F. W. Quidas, Mount Washington, Md., 606,792. Filed July 22, 1897. Designed for street car use.

COMPOSITION OF MATTER FOR ELECTRIC HEATERS. G. B. Fraley, Philadelphia, Pa., 606,921. Filed Aug. 12, 1897. Consists of talc, silicate of soda, carbonate of soda and water in suitable proportions.

Railways and Appliances:—

ELECTRIC RAILWAY. J. C. Henry, Denver, Col., 606,663. Filed March 28, 1896. An electric circuit controlling device comprising two relatively movable contacts, one being rotatably adjustable so as to present different contact surfaces, and means for clamping the contact in adjusted position.

ELECTRIC RAILWAY. J. C. Henry, Denver, Col., 606,664. Filed April 7, 1898. Consists of decreasing the resistance of the field magnet circuit of one motor so as to increase the energization of the field magnet of the other motor and correspondingly decrease the armature current of the other motor.

TROLLEY HEAD. C. Grover, Kansas City, Mo., 606,711. Filed Nov. 18, 1897. Details of construction.

CONTACT DEVICE FOR ELECTRICALLY PROPELLED VEHICLES. H. P. Davis, Pittsburgh, Pa., 606,819. Filed April 6, 1896. Comprises a roller, a supporting head formed of two sheet-metal strips of different shape rigidly fastened together and provided with suitable bearings for the roller, laterally extending guard and brace rods and curved tapering, sheet-metal plates forming continuations of the contact surface of the roller.

CONTACT DEVICE FOR ELECTRIC RAILWAYS. C. A. Terry, New York, and H. P. Davis, Pittsburgh, Pa., 606,825. Filed March 2, 1896. Consists of a revolving cylinder, a fork carrying the same, stationary pieces at the end of the roller constituting continuations thereof and tapering outwardly, and a supporting arm rigidly joined at its upper end directly to the fork.

CURRENT COLLECTING APPARATUS FOR ELECTRIC RAILWAYS. C. A. Terry, New York, and H. P. Davis, Pittsburgh, Pa., 606,826. Filed April 6, 1896. Comprises a contact supporting arm and a pivoted base to which the arm is hinged, a locking device normally

acting to hold the base against the movement on its pivot, and means actuated by the downward movement of the arm to unlock the base.

OVERHEAD CONSTRUCTION FOR ELECTRIC RAILWAYS. C. A. Terry, New York, and H. P. Davis, Pittsburg, Pa., 606,827. Filed June 10, 1896. A section insulated from the main portion, an auxiliary section bridging the insulated section, a second supply conductor crossing the insulated section and a casting having guiding arms respectively fastened to the insulated section and to the conductor crossing it.

TRAVELING CONTACT DEVICE FOR ELECTRIC RAILWAYS. G. Westinghouse, Pittsburg, Pa., 606,828. Filed April 6, 1896. A current collecting device for electrically propelled vehicles, comprising a reversible support and means for locking it in either of two positions, and a circuit closing device, one member of which is carried by the support.

ELECTRIC BRAKE. H. P. Davis, Pittsburg, Pa., 606,917. Filed Oct. 22, 1897. Comprises a plurality of electric motors arranged in parallel in a local circuit to be driven as generators, combined with a plurality of brake magnets, one in each branch of the circuit.

ELECTRIC RAILWAY. J. C. Henry, Denver, Col., 606,990. Filed April 18, 1898. Means for changing the armatures of a two-motor car equipment from series to parallel relation without excessive change or current strength.

ELECTRIC RAILWAY. J. C. Henry, Denver, Col., 606,991. Filed April 25, 1898. Similar to above.

Switches, Cut-Outs, Rheostats, Etc.:-

RHEOSTAT. H. B. Cutter, Philadelphia., 606,646. Filed June 22, 1897. Comprises a rheostat, an automatic magnetic circuit-breaker, automatic means of preventing the closing of the circuit-breaker when the rheostat arm is in certain positions and means of manually interrupting the flow of current through the automatic magnetic circuit-breaker to cause its arbitrary actuation.

ELECTRIC LIGHT SWITCH. F. L. Temple, St. Johns, Canada, 606,746. Filed Oct. 7, 1897. Means whereby the withdrawal of the key from the door of a room after locking it will extinguish the light.

ELECTRIC HEATER OR RHEOSTAT. R. Van R. Sill, New York, 606,769. Filed May 29, 1897. Consists of an outer shell and a resistance filling therein in the form of a spiral layer of comminuted material with the convolutions in contact.

FUSE BOX. J. B. Smith, Manchester, N. H., 606,771. Filed Feb. 23, 1897. Details of construction.

ELECTRIC SNAP SWITCH. A. F. Wood, Philadelphia, Pa., 606,884. Filed Oct. 8, 1897. Details of construction.

LIGHTNING ARRESTER. W. E. Athearn, Brooklyn, N. Y., 606,954. Filed Aug. 9, 1897. Comprises a spiral spring retained on a porcelain block by a fusible wire.

Telegraphy :-

MACHINE FOR PUNCHING TELEGRAPHIC PAPER. G. M. Gibson, Chulmleigh, England, 606,658. Filed July 26, 1897. Details of construction.

Telephones:-

TELEPHONE EXCHANGE. F. A. Lindquist, Chicago, Ill., 606,764. Filed May 19, 1897. Details of construction.

TELEPHONE SYSTEM. B. R. Dodge, Post Mill Village, Vt., 606,803. Filed June 17, 1897. Party line system.

TELEPHONIC TRANSMITTER. T. F. Ahern, Detroit, Mich., 606,852. Filed June 19, 1897. Consists of two substantially triangular carbon electrodes placed in frictional contact, the area of which is varied by the sound vibrations of the diaphragm carrying one of the electrodes.

MEANS FOR PREVENTING DISTURBANCES IN TELEPHONIC CIRCUITS. O. T. Blathy and K. De Kando, Buda-pesth, Austria-Hungary, 606,912. Filed April 27, 1897. Employs monophase or polyphase alternating current plants which have one of the conductors grounded, with alternating currents of a frequency less than twenty complete periods per second, in combination with monophase or polyphase alternating current motors with slantwise slots, for preventing disturbing influence on telephone apparatus.

REPORTS OF COMPANIES

Nassau Electric Railway Readjustment.

The readjustment of the securities of the Nassau Electric Railway Company and its leased and controlled companies is practically completed. The consent of the stockholders has been secured, and the Kings County Traction Company's shareholders have turned in all their stock. Under the plan the capital of the Nassau Company is increased sufficiently to absorb all the other companies. The new company will have a capitalization of \$6,500,000 of 4 per cent. preferred stock, and about \$8,000,000 of common stock. It will also issue \$13,500,000 of 4 per cent. bonds, \$1,500,000 of which are to be held in the treasury. The new common stock will be distributed among the present common stockholders pro rata. The bondholders exchange their 5 per cent. bonds for the new 4 per cent. bonds and 20 per cent. in preferred stock. The bondholders of the Atlantic Avenue Railroad first and consolidated 5 per cent. mortgage bonds receive new 4 per cent. bonds and a 25 per cent. bonus in preferred stock. The floating debt of \$1,500,000 is to be paid off.

The Outlook For General Electric.

According to calculations by the New York News Bureau the General Electric Company, with its present earnings, will, under the proposed plan, be able to show 6 or 7 per cent. earned on the common stock. The company, as is well known, is doing a business which taxes the capacity of its entire plant.

If its net earnings in the year to end January 31, 1899, should increase only 10 per cent. (about the amount of the gain in 1898 over 1897), with the debenture interest payable on only \$6,000,000 bonds, the next General Electric report would make an exhibit somewhat like the following:

Net earnings to Jan. 31, 1898.....	\$1,797,246
Estimated 10 per cent. increase.....	179,724

Net for year ending Jan. 31, 1899.....	\$1,976,970
Other income basis 1898	\$389,789
Less interest on debentures	300,000
	89,789

Total	\$2,066,759
Amount written off 1898	\$752,221
Less profit on securities sold	130,371
	621,850

Balance	\$1,444,909
Preferred stock, 7 per cent.....	178,584

Balance	\$1,266,325
Common stock, 6 per cent.....	1,096,560

Surplus	\$169,765
---------------	-----------

The surplus, it will be seen, is in excess of 6 per cent. on the preferred stock, which might be devoted toward the cancellation of the back dividends on that stock."

The committee of preferred stockholders will, it is said, oppose resolutely the new plan of adjustment.

Meeting of the Phoenix Carbon Co.

A meeting of the shareholders of the Phoenix Carbon Manufacturing Company, by direction of the Board of Directors, will be held at the office of said company, St. Louis, on August 31st, for the purpose of considering and acting upon a proposition to increase the capital stock of said company from \$160,000, the present amount, to \$500,000. This increase of capital is rendered necessary by the steady and large growth of the company's business and the very bright outlook for the future.

Mullinix Electric Co.

The Mullinix Electric Company has been organized at Cincinnati, O., to manufacture specialties in the electrical line. The general manager of the new concern, Mr. C. L. Mullinix, was formerly a member of the firm doing business as the Ohio Electric Specialty Manufacturing Company, of Troy, O. He was the designer of the line of woven wire brushes made by that company. The new enterprise will put all Mr. Mullinix's ideas into shape for the market.

Midsummer Quietness.

In spite of war, the general business and attitude of the country is peaceful, in the usual midsummer way, when vacations are in order, factories are cleaned up and a certain amount of stock-taking is done. The crop outlook continues excellent, and the farmers are apparently all doing well and juying well. Chicago reports a very large trade in all lines. Our grain exports are still heavy, and exports in general are maintained at a good rate. Bank clearings were 5.6 per cent. larger than in the week of 1897, and 40 per cent. larger than in 1894. Railroad earnings for the first half of the year show up finely, the bulk of the traffic being enormous, while economy in management makes the net better all around. Only 5 per cent. of the railroad mileage of the United States is now in receivers' hands, whereas in 1894 it was 20 per cent.

During the week 10,874 shares of Western Union were sold around 93½. General Electric has become more active, 19,527 shares exchanging hands at 39½ to 40. In Boston, on less than 300 shares Bell Telephone, went off 5 points to 275.

Wiring the New York State Capitol.

A VERY interesting contract for wiring has just been carried out at the New York State Capitol, Albany, by the E. G. Bernard Company, of Troy, N. Y. The firm undertook to do the job in thirty working days and finished with five days to spare, although ninety days were required by other concerns, and Mr. Perry, the State architect, regarded sixty days as the limit. One of the main features was the drilling of about sixty newel posts of Hallowell granite. Within twenty-four hours after the receipt of the order, the Bernard company had seven steam drills at work, and this task was accomplished in about eighteen days. In each post a vertical hole from 9 to 17 feet long and 2 inches in diameter had to be drilled and to be met exactly by a horizontal hole from 4 to 8 feet long and drilled in a duct hardly large enough for a man to crawl into. The contract included over 7,000 lights. More than 2,000 of these were for lighting the "million dollar" library staircase, over 1,000 going in the dome of the staircase alone, the remainder of the lights being divided in the four approaches and new addition to the State library, with full complement of switchboard, mains, feeders, branches, etc. All wire used on the job was special, so that no standard marketable size could be used for the heavy work. In this installation the Bernard company employed about 75 men, and it was a case of rush from beginning to end. This record is a striking proof of the ability of the Bernard company to handle large and special work in their line in the shortest possible time limit, and there can certainly be no red tape in their management, or work of this magnitude could not be accomplished in so short a time, especially when all wire and other factories were rushed to their utmost capacity with Government orders. The Bernard company claim they could have finished the work in twenty days if standard goods had been specified. They also claim this is the largest and most difficult contract for concealed work in a finished building ever executed in the United States.

Harrisburg Foundry and Machine Company, Harrisburg, Pa.

FEW names of engines are more familiar to the users of steam or to people at all acquainted with street railway and electric lighting power plants than those of "Ide" and "Ideal," two names which have made the manufacturers of these engines both prosperous and prominent. Familiar as these names have been, however, they are about to be surpassed by a third, that of the "Standard," or "Harrisburg Standard," this being the name given to a new engine just brought out by the firm, or, rather, just put on the market, for some of the machines have been running for some time, and thoroughly tested, and have made a record that justifies the claims that are being made for the new-comer. This engine is built on the same general line of the others, and retains all the essential features of the other two, but differs from them as the superlative in language differs from the positive and comparative, so that the names Ide, Ideal and Standard, when compared, read good, better, best.

The main features, however, of this new machine, we are not yet permitted to describe, but it will be illustrated in the course of time. It is enough to know that no cheap material or work enters into its construction, for the same care in workmanship and finish as has been characteristic of all the products of this firm will be exercised in this, and purchasers can feel confident of getting a machine that will last for an unlimited period, and certainly as long as some of the company's older engines, one of which has now been furnishing the power in the company's machine shop for the last twelve years, with little or no attention, except to start and stop it, and with a repair account that is nil. The engines are self-oiling, as the disc with crank pin is enclosed in an oil-tight case and run in a bath of oil, which, by the rotative motion, is forced through pipes to all the bearings of the engine, this being effected without any added mechanism to the engine proper. The new engine will be built to any de-

sired capacity from 8 to 500 h. p., and both simple and cross compound.

The finish and adjustment of the governing mechanism of these engines is of special interest to one at all familiar with the different methods of speed regulation. The fly-wheel type of governor is employed, and the main balance levers are mounted on case-hardened polished pins, with roller bearings, and all the auxiliary bearings are also provided with anti-friction bearings, almost removing friction and making the mechanism unusually sensitive. This governor is centrally balanced and remains so at all points of motion or cut-off, a decided advantage.

The works of the company occupy a tract of eighteen acres on Allison Hill, a height overlooking Harrisburg. The shops comprise four large buildings, known as the machine shop, wood shop, boiler shop and foundry. The tool equipment is very complete, and the labor-saving devices in the way of trolley hoists, cranes and trucks for handling material are numerous and ingenious, among which may be noted a bicycle jib crane, which is guided by a floor and overhead track, which gives a freedom and range of movement that is very remarkable, and makes it a very desirable equipment for any shop. The machine shop is a brick building in the form of a double L, with a boiler and engine room between. The tools of the finishing department, consisting of emery grinders and other tools, by means of which the crank pins, piston rings and other close-fitting parts are polished and gauged, are of peculiar design and economical in operation. Micrometer measurements are made and records and templates kept of all the wearing parts of every machine turned out, so that any piece can be duplicated to replace a worn or broken part, even after a period of twenty years, should an order be received. The products of the firm are not confined to engines, but they build tubular steam boilers of all sizes, and steam road rollers, which include an engine, a boiler and a cab. The tool equipment of the boiler shop includes a very large hydraulic riveting machine and means for handling the large shells. In constructing the boiler the ends of the tube are battered over by hand, and all rivets are finished by hand after coming from the riveting machine, making the work very neat and safe. The company insist that tubular boilers are holding their own against the claims of any other type of boiler in efficiency and economy, and refer to a test of a battery of boilers which they had installed, having Witmeyer settings, and which was made by William Sellers & Co. for some special purpose, and which, under an eleven hour test, showed an evaporation of 13.12 pounds of water per pound of coal from and at 212 degrees. Notwithstanding the magnitude and equipment of the plant as above described, it is the intention of the company to rebuild and enlarge the works in the near future and put in an additional equipment, in order to meet the demands of their growing trade, which is now greatly overtaxing the facilities. Mr. William R. Fleming, formerly the Eastern agent of the company at New York, is now vice-president and general manager at the works, having been induced to accept this position in February last, and is pushing along improvements to keep pace with the increased demand for the new engines and the general products of the concern. They are now building complete plants for six electric railways, besides a large amount of isolated plant work. At this writing they report 47 engine orders undelivered, from which may be gained a fair idea of the volume of business being done in these shops.

Ohio Electric Specialty Co.

Mr. J. R. Simpson is now the sole proprietor of the Ohio Electrical Specialty Company, of Troy, O., and writes to inform us that it is doing a larger business than ever before in its history. Brushes, rheostats and other specialties of its manufacture have all found favor with the electrical trade throughout the United States and in some foreign countries, and all further orders will be filled with the same promptness and dispatch, all work being guaranteed. Inquiries are solicited.

SUMTER, S. C. The annual meeting of the Telephone Manufacturing Company has just been held and the results reported were so good that the capacity and output of the factory will be doubled. During the year the company has shipped telephones all over the Union, as well as to Mexico, Canada and Central America, and has sold a number of its Imperial long-distance apparatus to the Government.

The Edison Store on Upper Broadway, New York.

UPPER BROADWAY has no finer modern office building than the St. James, at the corner of 26th street. Its 16 stories tower up above everything in the neighborhood. The

on both Broadway and 26th street are of light sandstone and red brick. The store itself has a floor space of some 5,000 square feet. Over the front entrance is a graceful glass awning, which together with the broad show windows, makes the lighting as nearly perfect as possible. At night the illumination of the store is a flood of radiance, as befits the company headquarters of

NEW HEADQUARTERS OF EDISON MFG. CO., NEW YORK CITY.

INTERIOR OF NEW EDISON STORE, NEW YORK CITY.

ground floor corner store is shown in the picture, and gives one an idea of the pleasing architectural effects which make them a landmark in the uptown shopping district. The facades

one whose name is occasionally mentioned in connection with the electric light. The magic signature is executed on the dark background of the signs over the doors in miniature incandes-

cent lamps. Nothing could be more attractive than the exterior, and nothing more satisfactory than the interior. The store is high and broad and long. Down the centre is a row of massive gilded columns. The walls are done in Pompeian red; the ceilings and cornices are of antique ivory finish. Fittings of polished oak with frosted glass in doors and partitions separate the spacious offices from the main room. The hardwood floors are carpeted with broad strips of Axminster, giving an air of luxury and elegance usually found in boudoir or drawing room, and not looked for in a show room.

Downstairs, the basement is as roomy as the store itself. Under the sidewalks are the wrapping and packing rooms, and also the adjusting and testing departments. There are a number of small rooms fitted up cosily, where buyers of records for their phonographs may hear them undisturbed. A stock of 15,000 makes buying easy; you can always get just what you want. There is also in the basement a fine "dark room," 50 feet long, permitting the proper display of moving picture films for the projecting kinetoscope; and a special show room for X-ray demonstrations, where the wonders of the cathode ray are exhibited, together with all the special apparatus used.

It is worthy of note that the goods displayed do not suffer by reason of their gorgeous setting; for their excellence, perfect finish and high grade, warrant every penny of expenditure in making this place one of the most attractive salesrooms on Broadway. The entire line of Edison phonographs is exhibited, from the most complete and costly down to the popular priced latest invention, the "Standard." Edison fans of various styles and sizes make the hottest, closest day agreeable. All types of the effective Edison-Lalande batteries are shown, while dental motors and a most complete line of electro-medical apparatus are the envy of every doctor or dentist who visits the store to see the very latest developments in the art.

A corps of polite and attentive salesmen are always ready to explain and demonstrate, or to use their arts of persuasion on customers who come prepared to be separated from their money on the basis of lawful and profitable "quid pro quo." Whether buying or looking around, all are welcome, and a visit to this store is already reckoned one of the sights of the metropolis.

Walker Generators for Making Calcium Carbide.

The Walker Company, of Cleveland, O., has secured a large and important contract from the Union Carbide Company, of Chicago, which is said to be the largest order for electric machinery of the alternating type ever placed at one time.

The order consists of twenty 500 h. p. alternating current generators, single phase, 60 cycles, to deliver a current of 2,500 amperes at 200 volts. Besides these, there will be five 100 h. p. direct current generators as exciters, and a complete switch-board for all of these machines.

The spot selected for this mammoth plant, which is to be run entirely by water power, is at the falls of the Soo at Sault Ste. Marie.

The Union Carbide Company has acquired rights of manufacture of calcium carbide for the United States and will have its main works at Sault Ste. Marie. The carbide is at present manufactured at Niagara Falls, the electric power necessary being supplied by the Niagara Falls Power Company. The output of the Niagara plant is about ten tons per day, while that of the works at the Soo will be 100 tons per day. The works are to be built for the accommodation of forty generators and forty electric furnaces, where the lime and carbon are fused into calcium carbide, the twenty generators in this first contract being but the initial order.

Recent Shipments By M. C. Bullock Mfg. Co.

We give below a list of recent shipments from the works of the M. C. Bullock Manufacturing Company, 1170 West Lake street, Chicago, including only the larger orders. The concern reports that business has been gradually and steadily improving for the past half year, so that the total shipments for the month of May aggregate larger than those of any month since the financial crash of 1893. Machinery business and that of mining in particular they find excellent. The orders are:

One 4 ft., two 6 ft. and one 8 ft. Champion mine ventilating fans to Japan. One "Detector" diamond prospecting drill, with complete outfit to bore and remove cores to a depth of 2,500

feet, shipped to Montana. One "Chief" diamond core drill, with complete outfit for removing a 2-inch core to a depth of 1,500 feet, for use in the Siberian gold mines of Russia. To the Metropolitan Iron and Land Company, of Ironwood, Mich., a "high-class" first motion hoisting plant, consisting of a pair of 24 x 48 Bullock-Corliss engines, with two cast-iron shell drums, 8 ft. diameter by 9 ft. face, each winding 2,075 feet of 1¼-inch steel wire rope. This plant is fitted with an auxiliary steam actuated handling motion, containing all recent refinements and improvements to insure safety and ease of manipulation. This is the fourth hoisting plant furnished to the above company by the Bullock Manufacturing Company. This fact speaks volumes for the character of the work turned out by this firm.

Chloride of Silver Dry Cell Battery Co.

THE principal products of this firm, as the name implies, are batteries, composed of chloride of silver dry cells, designed chiefly for use by physicians and dentists, and are known as medical batteries. Both the galvanic and faradic types are manufactured, and as accessories a very large assortment of electrodes are made.

This type of battery until recently has been employed almost entirely in medical practice, but now they are being used by electric lighting, telephone and street railway companies for the testing of cables and conduit wires. These batteries on account of their compactness and lightness are especially adapted for use in subways and out-of-the-way places where it is difficult to use large testing instruments, and to this class of trade the manufacturers are now catering. The principal claims made for this type of cell are its extreme lightness, durability, a constant potential throughout the life of the battery and mechanical construction and finish.

The individual cells are extremely small, being less than an inch in diameter and a trifle over 3 inches in length, including the brass tube in which each cell is encased, and weigh only about 2 ounces; they are made to an exact gauge, so that the cells may be readily replaced, and as may be inferred, a 50-cell battery can be mounted in a small case which can be easily handled. No liquids or acids are used in the manufacture, so that each cell is practically dry, being hermetically sealed, and then enclosed in a close fitting brass tube, so that a battery can be carried in any position without a possibility of leakage. The composition and construction are covered by numerous patents. The tension of each cell is one volt. Each cell has an actual working life of 700 hours and gives a constant electromotive force during its entire life, which is measured only by the actual demand made upon it, there being no chemical action when the circuit is not closed, so there is practically no limit to the time the batteries will last, and many that were put in service ten years ago are reported still as being in good working condition. The price of each cell is 90 cents, but the cells when exhausted may be returned to the manufacturers for which the company allows 60 cents, as the silver element, which the cell contains is valuable, and can be refined and used again. By this arrangement cells can be accepted in exchange for new ones at two-thirds the original price. The rheostat employed with these batteries is of special design, and known as the Willms' current controller; it consists of a circular disc about 6 inches in diameter, mounted on a metal base, and having on its face a hard rubber plate, perforated around the edge with contact pins, which connect with the graphite resistance placed between the rubber and base. The switch arm is pivoted in the middle, and as it swings around it gradually cuts out the resistance; the range being from less than one ohm to a maximum of 200,000 ohms. Controllers of this type are also calibrated, showing the amount of resistance at each contact point.

This firm, of which Manes E. Fuld is general manager and H. S. Shepard superintendent, have been in the business about fifteen years; their office and works are located at 409 Paca street, Baltimore, Md., where they occupy two buildings, extending through the block. The power for operating the machinery is supplied by a 50 h. p. gasoline engine, and the different departments are well equipped with the necessary metal and iron working tools. There is also a nickel-plating department, buffing wheels and ample storage and packing space. Light and dark mahogany are the woods chiefly employed for cases and

cabinets, and in all cases the cabinets are richly finished. About fifty hands are employed, and the products go to all parts of the world, China and Japan being liberal customers.

The Reliable Electric Mfg. Co.'s Telephone Apparatus.

A VERY complete and interesting catalogue has just been issued by the Reliable Electric Manufacturing Company, of Worcester, Mass., manufacturers of telephones, supplies and electrical specialties. The company make a specialty of high grade telephone apparatus. Their transmitter is claimed never to get out of order and yet is so delicately adjusted that the slightest sound can be distinctly heard, and at the same time it gives perfect articulation. It has been thoroughly tested for long distances and general use and has received the highest testimonials. Their complete telephone set No. 1 is intended for exchange and long distance use and is provided with their patented granular transmitter, a 15,000 ohm generator, powerful ringers and their double-pole receiver. The set is ornamental, as well as useful, and special finish and workmanship have been laid out on this instrument. Set No. 2 is intended for every class of service, and especially for intercommunicating systems. Set No. 3 is a battery call set for offices and other places where a nicely finished instrument is required. Set No. 4 is a combination desk set with switch arrangement in the base. This consists of an aluminum globe surmounted by a bronze eagle, which holds the telephone set and is adjustable in any position. Set No. 5 is a desk set with the transmitter adjustably mounted and equipped with a double-pole receiver. Set No. 6 is a combination transmitter and receiver. The company's receiver is one of the most powerful manufactured, and consists of a hard-rubber handle and bottom piece, nickel-plated brass case, silk-wound spools and double-pole magnets strongly magnetized. Set No. 7 is a high-grade instrument, without the costly finish given to set No. 1 and is furnished with a standard Bell receiver. Set No. 8 is intended for private lines and interior work in factories, warehouses and large stores. Set No. 9 is a battery call set fitted with their granular transmitter and a standard Bell receiver. All these sets are illustrated, and their prices given in the catalogue, which also contains numerous illustrations of other electrical specialties. The catalogue will be sent to anyone on application, and all questions relating to these goods will be cheerfully answered by the Reliable Electric Manufacturing Company, 86 Foster street, Worcester, Mass.

ADVERTISERS' HINTS

THE MUNICIPAL COUNCIL of Shanghai, China, advertise for proposals for furnishing two 100 k. w. alternators direct coupled to medium speed engines and for switchboard and instruments and a water tube boiler.

THE GENERAL ELECTRIC COMPANY call attention to the ease with which their enclosed arc lamps may be trimmed.

THE GARVIN MACHINE COMPANY, Spring and Varick streets, New York, offer shapers in all sizes and styles. They have a large stock for immediate shipment.

THE K. & W. COMPANY, Pittsfield, Mass., say that sustained candle power is the strong point of their lamps.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY devote their space to the type "C" Tesla polyphase induction motor.

KENT ELECTRIC MANUFACTURING COMPANY, Worcester, Mass., are supplying drum armature battery fan motors at \$6.00. They carry a 10-inch fan.

THE PELTON WATER WHEEL COMPANY, New York and San Francisco, have installed 9,000 wheels, which aggregate some 700,000 h. p.

THE BURTON ELECTRIC SMELTING COMPANY, Boston, Mass., suggest to central station managers that they

introduce the Burton electric forge, which will be found to fill a long-felt want in many fields of manufacturing.

NEW YORK NOTES

MULTIPHASE WIRE. The Suburban Underwriters' Association, New York, has increased the rebate allowed for the automatic fire alarm system to 10 per cent. when the boxes are connected by means of the Montauk "Multiphase" wire, which has already made so favorable an impression on the electrical and insurance public.

BRUSH ELECTRIC COMPANY, through General Manager Hamill, reports the sale of 12 125 arc lighters to the Buffalo General Electric Company and states that it is busy on a variety of orders.

The Electrical Engineer.

Vol. XXVI.

JULY 21, 1898.

No. 533.

A Fourteen Mile Transmission at Barton, Vt; With Monocyclic Apparatus.

FOR the past two years the village of Barton, Vt., has been enjoying the benefits of cheap electricity brought to it by the Barton Electric Light and Power Association, from a water power situated fifteen miles distant at Charleston, Vt. Within

STONE DAM AND WOODEN TUBE, PLUNKETT'S FALLS, VT.

recent years Barton has been undergoing a steady process of growth, incident to the location within its limits of several large manufacturing concerns, and the increase of population which these have brought in their train. About two years ago it was felt that the town had reached the condition in which electric

GENERATING STATION, PLUNKETT'S FALLS, CLYDE RIVER, VT.

lighting had become a necessity, and the project took form by the appointment, by the townspeople, of a committee to investigate the matter and report. The question was very thoroughly examined and discussed, and every system canvassed. One mile east of West Charleston village on the Clyde River, is a water power known as Plunkett's Falls. This seemed to the committee a very suitable source of power which might be utilized in connection with the electric lighting project, and it was secured at a reasonable figure. At the next village meeting it was voted to build a plant and to locate it at Plunkett's

Falls. The trustees were empowered to bond the town in accordance with an act of the Legislature and to proceed with the work.

The power site is admirably suited to electric generation purposes. The stream is large, the flow comparatively uniform and with only ordinary precaution little danger of shut down is likely to occur from ice or freshets. The entire fall of water, 76 feet, is utilized.

A masonry dam 75 feet long was thrown across the river at Plunkett's Falls and from this to the power house forebay a flume or wooden pipe line, 1,000 feet long, was laid, 700 feet of which is laid upon a rock ledge along the Clyde gorge above the stream. The wooden pipe is built of heavy planking tongued and grooved and held together by heavy iron bands. The hydraulic work was carried out by G. W. Buzzell.

The system of generation and transmission adopted is the monocyclic system of the General Electric Company. The use of this system for a transmission of power over so great a distance is extraordinary and this is the only instance in which it has been employed. It has, however, been successfully operated without accident or difficulty since the day the plant was started.

The power house is a frame building standing on a rock ledge

LEFFEL WHEEL, GENERATING STATION, CHARLESTOWN, PLUNKETT'S FALLS.

near the stream, about one mile from Charleston village. It is divided into three parts, the lower or turbine chamber, the dynamo and switchboard room and the living room of the station attendant above the dynamo room. The turbine is from the works of the James Leffel Co., of Springfield, O. It runs at 350 revolutions per minute and is rated at 500 h. p. The dis-

GENERATING PLANT, CHARLESTOWN, PLUNKETT'S FALLS.

charge water passes into a tail race 200 feet long below the power house. The turbine is belted to two General Electric monocyclic alternators set up on the first floor. These are eight-

pole machines, each of 100 kilowatt capacity, delivering current at 1,040 volts at a speed of 900 revolutions per minute.

These alternators are simple single-phase generators differing slightly from the standard single-phase type, in the armature, which is provided with a small additional winding known as a "teaser" coil. By means of this coil an out-of-phase electromotive force is furnished for the purpose of starting motors.

INTERIOR OF SUB-STATION, BARTON, VT.

The monocyclic system is, however, essentially a single-phase system and practically all the energy is carried over two wires. From these the lighting system is supplied in the usual manner. The induction motors require a third or "power wire," but this is run only to points where motors are to be installed. Thus the lights are operated on a single-phase system, while the motors operate as on a multiphase system. In the monocyclic system unbalancing is impossible.

The armatures of these machines are of the ironclad type and the coils are formed and insulated before application to the core. They are held in place by insulating blocks and no binding wires are used. The armature is thoroughly ventilated, and built up of thin sheets of steel of high magnetic permeability. The frame is in two parts, the lower being the base, lower magnet yoke and the pillow blocks; the upper part being the upper magnet yoke. The pole pieces are made up of steel laminations cast into the yoke, and the field coils are wound on insulated removable spools. The machines run cool and

MAIN SWITCHBOARD, GENERATING PLANT.

regulate automatically. Each machine occupies a space of 6 ft. 8 in. long by 6 ft. 2 in. wide.

The switchboard is of the wooden skeleton type and all wires to and from it are carried underneath the floor. The step-up transformers are of the air-blast type and are four in number each of 40 kilowatt capacity. In these the initial pressure is raised, and the current passes to the transmission lines at 5,720 volts. One illustration shows a pole head near the entrance of the line into Barton. The topmost insulator supports an iron

barbed wire grounded at intervals and acting as a lightning arrester. The next three insulators arranged in a triangle are of the porcelain double petticoated type, and carry the three

POLE LINE, ENTERING TOWN OF BARTON.

main transmission wires of No. 4 B. & S. gauge. The next three are of glass and carry the secondary mains from the sub-station. The two lowest carry the telephone wires.

The substation at Barton is a small frame building carrying

SUB-STATION, BARTON, VT.

a tower into which the main transmission lines are brought and connected through G. E. alternating current lightning arresters to step-down transformers, each of 40 kilowatt capacity, also of the air-blast type. These are cooled by two 12-in. Sturtevant

EXCITERS AND WATER WHEEL GOVERNOR, CHARLESTOWN.

blowers—one coupled directly to an overshot water motor driven by water from the Barton water system, the other coupled directly to a 1 h. p. induction motor served from the long dis-

tance transmission lines. There are thus two methods of ventilating the transformers, but ordinarily the water motor only is in use, the electric motor being called upon in case of emergency. The transformers reduce the pressure of the current to 1,040 volts, at which pressure it is distributed over a system of feeders to smaller transformers, in which the pressure is again reduced to 113 volts.

The service network is laid out on the Edison three-wire system, and all current is supplied to customers through Thomson recording wattmeters. The lighting of the streets is effected by groups of two 16 candle power incandescent lamps, under a small reflector hood, located at short intervals along the streets and highways. They are directly connected to the secondary, three-wire Edison, network. This system of lighting was adopted because it allowed the use of one type of lamp only for all lighting purposes in Barton. Furthermore, the chance of both lamps failing is very greatly reduced, and as a matter of fact inspection of the street lamps is made once a week only. The number of 16 candle power lamps wired for residential and street lighting is 2,000.

The cost of operating this plant is, we are assured, exceedingly low, while the service rendered is highly satisfactory. The transmission line is carried also to the town of Island Pond, Vt., 12 miles away, where about 800 lights are supplied with the necessary current. The committee under which the project was started was made up of Messrs. C. P. Percival, Geo. H. Davis and J. W. Murkland. The general superintendency of the work was vested in the town trustees E. G. Colliston, H. T. Seaver and E. F. Dutton. The resident engineer, who superintended the details of the work, was Mr. Ernst Gonzenbach.

The Glasgow, Scotland, Municipal Lighting Plant, Port Dundas.

WE illustrate herewith in some detail the plans for the new Port Dundas plant of the Glasgow municipality, which will contain a good deal of American apparatus. These plans have been prepared by Mr. W. A. Chamen, the electrical engineer of the corporation, and the building was designed by Mr. Andrew Myles, in consultation with him. The portion of the building now being proceeded with is in the centre, and measures some 220 feet long. It will be capable of containing plant

FIG. 1.—ELEVATION OF GLASGOW MUNICIPAL LIGHTING PLANT, PORT DUNDAS.

equal to an output of 10,000 indicated horse power. The whole building, when ultimately completed, will be capable of containing plant equal to an output of 30,000 indicated horse power. The plant at present to be installed in these buildings consists of two Babcock and Wilcox boilers of about 1,100 h. p. each, carrying about 200 lbs. steam pressure and fitted with automatic stokers of the chainrate type; one triple-expansion vertical engine of 900 indicated horse power, made by Messrs. Matthew Paul & Co., Limited, of Dumbarton, directly coupled to multipolar dynamo by Messrs. Shuckert & Co., of Nurnburg, furnished by Messrs. Mavor & Coulson, Glasgow. One compound vertical engine of 750 indicated horse power by the Ball & Wood Company, directly coupled to two dynamos by the

Walker Manufacturing Company, the contract for this being in the hands of Messrs. Laing, Wharton & Down, of London. One 400 h. p. triple-expansion vertical engine by Messrs. Mirlees, Watson, Yaryan & Co., Limited, and one 200 indicated horse power compound vertical engine by the same makers, each being directly coupled to dynamos by Messrs. Crompton & Co., Chelmsford, the contract for these two sets being in the hands of Messrs. Mirlees, Watson, Yaryan & Co., Limited.

The Forth and Clyde Canal lies at a considerably higher level than the engine room floor, and the ground falls away rapidly from the canal to the roadway. Although this necessitates dif-

FIG. 2.—PLAN OF PORT DUNDAS PLANT.

ferent levels for the floors of the coal store, boiler house, engine room and battery room, it offers advantages in the supply of fuel. The coal will be brought in by canal and lifted by the Temperley transporter direct from the barges, and deposited either into the coal store or into weighing hoppers placed above the coal tanks on the top of the wall between the coal store and the boiler house. From this tank it can be shot either into the coal store or into the hoppers of the automatic stokers, along the boiler fronts. The ashes from the boiler furnaces are delivered into a tunnel or subway running from end to end of the boiler room and arranged so that shallow trucks can receive the ashes and carry them to the ends, where they can be lifted and shot into carts or otherwise disposed of.

There will be only one line of boilers, each unit of which will be of about 1,100 h. p. There is a space behind the boilers

FIG. 3.—SECTIONAL VIEW, PORT DUNDAS PLANT.

sufficiently large to take economizers, the three chimneys dividing the space into four lengths. Two of the chimneys will be at least 230 feet high and 13 feet in diameter, and the centre one 200 feet high and 11 feet in diameter. All steam pipes will be as far as possible in the boiler room, and there will be no ring main of steam pipe entailing the use of large valves which are so troublesome to keep tight. Arrangements will be made so that the main steam pipe can be relieved of all pressure at certain times without stopping the station.

The engine room is about 57 feet in width and is spanned by a traveling crane capable of carrying 25 tons, so that it will be capable of dealing with sets of plant up to 2,500 h. p. in size. Next the wall of the boiler house is a trench along which water tanks on weighing machines can be run for the purpose of measuring the condensed steam from the air pump of any engine which may be under test. All the large sizes of engines will be fitted with separate surface condensers, having the air pumps either driven directly by rocking shaft and connecting rods or by electric motors. The cooling water will be taken from the canal at one end of the engine house and returned to it at the other, the necessary pumps for overcoming the pipe and condenser friction being of the centrifugal type and driven by electric motors. Owing to the position of the canal very little power should be required for forcing the circulating water. On the left-hand side of the engine room tunnels are provided for the cables to and from the dynamos, switchboards and feeders.

The roofs of both engine and boiler rooms will be entirely of iron and glass so as to give ample light.

Next to the engine room comes the battery room, which is divided in the middle by the entrance under the tower containing the station engineer's office, etc. An important feature of the design is that the station engineer's office has in it a bay-window projecting into the engine room, so that he can see from end to end of it without leaving his room. By means of a spiral staircase he can also obtain access to a gangway overhead, which passes across the engine room above the level of the traveler and thence also across the boiler house, so that he can, with the minimum amount of walking and in the shortest possible time make an inspection of the whole premises.

Two-Wire Distributing Systems and Lamps, 200-240 Volts.¹

BY JOHN W. HOWELL.

DISTRIBUTING systems, operating at 200-240 volts with simple two-wire circuits, first attracted attention about four or five years ago. These early plants used two 110-120-volt lamps in series and were installed as a means of competing in cost of installation with three-wire plants without resorting to the alternating current system, with its disadvantages where motors are operated. The growth of these plants was slow until the demand created by them led to the production of the 200-240-volt lamp and practical experience had shown the weakness of these lamps and led the makers to overcome the difficulties met in their manufacture.

These defects have been entirely remedied, and the experience of many plants operating 200-240-volt lamps during the past year proves these lamps to be just as reliable in service as are 110-volt lamps. The development of the lamp has taken considerable time, and the growth of the 200-240-volt two-wire system in spite of the shortcoming of the early lamp is due to compensating advantages in other elements of the system.

These advantages over the three-wire system are: (1) cheapness of installation and (2) simplicity of operation.

1.—Cheapness of installation of the 200-240-volt two-wire system, when compared with the 110-120-volt three-wire system, arises from the use of a single large dynamo where the three-wire system requires two, each having half the capacity; with the accompanying duplication of regulating apparatus, indicators, ammeters, etc. There is also a saving of the entire cost of the neutral conductor of the three-wire system, which conductor in street mains (as distinguished from feeders) and in house wiring, should be as large as the outside wires.

Three-wire plants in cities, whose business warrants the employment of the skill necessary to operate the system to best advantage, successfully use 110-120-volt 3.1 watts per candle lamps and get very excellent results from them. The 200-240-volt two-wire system cannot be considered a competitor of the three-wire system under these conditions since the best 200-240-volt lamp on the market to-day is a four watts per candle lamp. But it is my opinion that in smaller installations, whose conditions call for a 3.5 watts per candle lamp when a 110-120-volt three-wire system is used, the advantages of the two-wire 200-240-volt system are sufficient to offset the disadvantages of a 4 as compared with a 3.4 watts per candle lamp. Under normal conditions the performance of the present four watts per candle 200-240-volt lamp as regards life and maintenance of candle power is about 25 per cent. poorer than the present 3.5 watts per candle—110-120-volt lamp, but it is my opinion that the greater irregularities in pressure ordinarily found in the three-wire plants we are now considering, as compared with the two-wire plants operated under similar conditions, fully counteracts, by its injurious effects upon the lamps, the advantage in life and candle power which the 110-120-volt 3.5 watts per candle lamp has under normal conditions over the 200-240-volt four watts per candle lamp.

In considering the relative advantages of the two systems, in the case of moderate sized plants above referred to, we must charge against the saving effected in a two-wire plant by its single equipment and omission of the neutral conductor, the increased capacity of machinery and conductors made necessary by a four watts per candle as compared with a 3.5 watts per candle lamp.

Considering the copper required by a 220-volt two-wire system using four w. p. c. lamps as our unit, the copper required by the two outside conductors of a 110-volt three-wire system using 3.5 w. p. c. lamps will be .875. The amount to be added to this for the neutral conductor will vary somewhat with location of the station with reference to the points of consumption. If we assume that one-half the copper is installed for feeders and one-half for the distributing mains, and that the neutral wire is one-third the size of the outside wire in feeders and the same size in mains, then the total copper in the neutral conductors of feeders and mains will be 29 per cent. of the amount used in the two-wire 220-volt system, and the total copper used in the 110-volt three-wire system will be 16 per cent. greater than the copper used in the 220-volt two-wire system. This comparison of the costs of copper does not consider the cost of wiring customers' premises, which is usually borne by the customer; it is, however, an advantage to the 220-volt system that this wiring will require at least 20 per cent. more copper for the three-wire 110-volt system than for the 220-volt two-wire system.

The 4 w. p. c., as compared with the 3.5 w. p. c. lamp, would require for the 200-240-volt two-wire system, one-seventh greater capacity of boilers, engines and dynamos than would be required for the three-wire 110-120-volt system.

The duplication of apparatus required for the three-wire system will only partly offset this increased cost in the two-wire 200-240-volt system, but the cost of this duplication of apparatus, together with the increased cost of copper required, will in many cases make the cost of installation of the three-wire system at least equal to that of the 200-240-volt two-wire system, leaving the simplicity of operation of the two-wire system to be balanced against the increased cost of fuel required to operate 4 w. p. c., as compared with 3.5 w. p. c. lamps.

During the time the plant is operated considerably below its rated capacity, which will probably cover even the maximum load during the first year of the plant's existence, and all but three or four hours per day at all times, I think the increased fuel consumption due to 4 w. p. c. lamps will not be appreciable because of the poor efficiency of boilers and engines with light loads, and the total increased consumption of coal during the year will, I believe, be a small consideration under most circumstances, and in my opinion not enough to balance the simplicity of operation above noted.

A few months ago I made a trip through some of our central States, visiting a number of 200-240-volt plants to get a knowledge of the practical workings of the systems from the persons actually operating them, hoping to get from their experience, information concerning existing conditions which would be of value in the lamp factory.

Naturally, my first questions to the man who operated the plant concerned the lamps; were they generally satisfactory? were they long lived? did they ever explode? I was greatly pleased with the answers I received. The lamps were reported to be almost universally satisfactory. They were very long lived, in fact too long lived, for better service would be rendered if the lamps were renewed when they began to get dull, and not allowed to remain in service after they ceased to give a first-class light.

These 4 w. p. c. 200-240-volt lamps may be used for 600 hours and still give a good light, but I think this is about the limit of their useful life. If not taken in they will keep on burning for a long time and will give an average life of over double that figure before breaking.

The reports concerning exploding were equally satisfactory. For the past year or more, exploding lamps had been practically unknown; previous to that time, however, this had been one of the most serious objections to the system.

All these plants have been installed with switches, cut-outs, and other appliances made for 110-120-volt installations, and it is remarkable how little trouble has been caused by them.

Sockets.—Ordinary key sockets have been freely used and experience has shown the Edison screw socket and lamp base to be preferable to other types. Some engineers recommend keyless sockets and good snap switches, to avoid possible failure of the key socket to break the circuit.

In order to get the desired factor of safety, the General Electric Company has recently developed a special key socket for this work, having a break gap twice as great as the sockets designed for 110-120-volt systems, and having a fibre insulating lining between the outside shell of the socket and the screw shell which is connected with the circuit. This fibre lining projects

¹Read before the 15th General Meeting of the American Institute of Electrical Engineers, Omaha, June 27th, 1898. Abstract.

sufficiently beyond the screw shell to prevent contact with the circuit when the lamp is in the socket. The lamps are provided with short bases designed to be completely covered by this fibre lining, so it is impossible to get a shock by touching the lamp when it is burning.

Flexible Cord.—Flexible cord has been freely used, and is all right if the best quality is used. For this purpose the conductors should be covered with rubber 1-32 inch thick and the outside covering should be silk, or if cotton it should be slicked with a compound which makes it non-inflammable.

Rosettes.—Rosettes designed for 110-120-volt circuits having fuses, have given a good deal of trouble, so it has become good practice to leave out the fuse wire and put copper wire in its place, thus having no fuse between the lamp and the fuse block close to the switch controlling the circuit.

The General Electric Company has produced a new porcelain rosette which has fuse wires over one inch long; these have been severely tested with very satisfactory results. Their use with fuses will give protection to individual lamps, which is very desirable, as it increases the safety of the wiring.

Cut-Outs.—Fusible cut-outs designed for 110-120-volts, have failed in many instances, and have often proved much more fusible than their makers expected them to be. A complete line of fuse blocks carrying special 200-240-volt fuses has been developed recently by the General Electric Company.

Switches.—Standard knife switches or quick-acting snap-switches having large break distances, should be used. Such switches specially designed for 200-240-volt installations are now being developed.

Wiring.—Standard methods of wiring for 110-120-volts are approved for 200-240-volts. Good rubber covered wire run on porcelain knobs or cleats is specified by the fire underwriters.

Arc Lamps.—Good arc lamps burning two in series on 220-volt circuits are on the market. Each lamp is provided with an automatic cut-out which throws an equivalent resistance into the circuit when one lamp is extinguished, thus permitting the use of one lamp if desired.

Future.—The future of the 200-240-volt system depends largely upon the development of a more economical lamp. All other elements of the system can be made entirely satisfactory with the means and knowledge now at our command, but the production of a more economical lamp calls for an advance in the art of lamp manufacture. That this advance will be made and a more economical lamp will be produced, I have no doubt, and hope to see such a lamp placed upon the market at an early date.

The Hull Alternating Arc Light Regulator.

MR. D. A. HULL, superintendent of the Port Clinton, O., Electric Light and Power Co., has recently secured a patent for a device for producing and regulating a constant current suitable for operating alternating current arc lamps in series.

The regulator illustrated in perspective in Fig. 1, consists of

FIG. 2.

an auto-converter connected across the mains, as shown in the diagram, Fig. 2.

The solenoid shown in the upper right hand corner of the engraving (Fig 1) is in the circuit with the lamps to be con-

trolled. It has under its control the induction motor which is cut in and out, and reversed according to the conditions of the circuit to be controlled. This motor operates the brush on a

FIG. 1.—HULL ALTERNATING ARC LIGHT REGULATOR.

series of contacts, which are connected with the leading out wires from the auto-converter located on the opposite side of the machine.

Storage Battery Plant of the Buffalo Street Railway.

BY ORRIN E. DUNLAP.

THOSE who attended the convention of the American Street Railway Association, held in Niagara Falls in October, 1897, will recall the interesting discussion that followed the reading of Mr. Charles Hewitt's paper on "Application of the Storage Battery to Electric Traction," and will perhaps remember that Mr. H. H. Littell, general manager of the Buffalo Railway Company, stated that his company had been told that they could save \$75,000 annually by the use of a battery. Since then the Buffalo Railway Company have installed a battery in connection with their power house and have started out to save all or a part of the promised amount.

The battery they have secured was made by the Electric Storage Battery Company, of Philadelphia, and it occupies a new fire-proof one-story brick building erected on the south side of the company's power house, on Niagara street. This building is most substantially constructed, and is in good keeping with the permanent improvements from time to time made by this progressive company, the officers of which are ever alert to do anything that will add to the efficiency of their service and station. The battery room is about 40 by 90 feet and has a concrete floor. A row of posts runs through the centre. There is a row of windows on one side, and at night incandescent lights furnish illumination. The capacity of the battery is 1,200 horse-power hours. It has 270 cells, connected in series. The tanks are 59 $\frac{7}{8}$ inches by 21 $\frac{1}{2}$ inches by 24 $\frac{3}{4}$ inches. The number of plates in each cell at present is 41, but provision

has been made so that a sufficient number of plates may be added to increase the capacity of the battery 66 2-3 per cent. without adding to or enlarging the tanks. This fact clearly demonstrates that the company have full confidence in the service of the battery. In size the plates used are 15 by 15½ inches.

STORAGE BATTERY PLANT, BUFFALO STREET RAILWAY.

The positive plates weigh 24 pounds and the negative plates 16 pounds. The weight of the battery is 21,000 pounds.

In connection with their battery the Buffalo Railway Company have installed a booster, which they have given position near the center of the main floor of the power house. This booster was made by the Western Electric Company. It is direct connected to a six-pole Western Electric motor of 220 kilowatts. It is good for 3,000 amperes at 70 volts. Its purpose is the regulation, charging and distribution of the current of the battery. A feature of it is that it has two commutators in parallel, their diameter being 29 inches and their length 21 inches. The density of the current under the brushes under full load is under 20 amperes per square inch. The dimensions of the whole unit are 150 inches, by 79 inches, by 84 inches high, the total weight being 45,000 pounds.

Just inside the battery room walls the ends of the battery are connected by leaded copper bus-bars to cables which run to the switchboard. This switchboard stands on a gallery in the main room of the station. The panels are of black marble. It is equipped with differential ammeters to show whether the bat-

BOOSTER, BUFFALO RAILWAY STORAGE BATTERY PLANT.

tery is charging or discharging. It also has differential voltmeters for the purpose of throwing the battery in parallel with the dynamos or rotary converters. There is a reversing switch connected with the shunt field of the booster for the purpose of changing the polarity of the booster to facilitate the charge and discharge. There are also two double pole switches, one of which is for the purpose of throwing the battery in parallel with the dynamos or converters, and the other for the purpose of throwing the battery through the booster or direct to earth, as circumstances call for.

Ventilation of the battery room is secured through ventilators in the ceiling, which allow the gases to pass off into the outside

air. A current of fresh air enters the battery room near the floor, and by this means the ventilation is made most perfect.

The Buffalo Railway Company now take 2,000 h. p. of the transmitted energy of Niagara. The peak of the load on the Buffalo system rises late in the afternoon, about 6 o'clock, and this the battery aids in meeting. From 7 a. m. to 7 p. m. the battery is operated in connection with the steam plant and with the converters during the night hours, until it is fully charged. During the early hours of the night the battery and converters take the load, and from about 9 p. m. to 1 a. m. the converters are charging the battery from Falls power.

The power house of the Buffalo Railway Company is a model of neatness in every particular. While the highest efficiency is demanded and obtained, economy is practiced at every point, and the claim is made that the actual cost of power per car mile is less in Buffalo than many other cities. The superintendent of the power house is Mr. Thomas Henning, who expresses great satisfaction with the battery installation and with the Niagara power service.

Notes From the Field—Electricity on the Pittsburg Street Railways.—I

BY C. B. FAIRCHILD.

"The world advances, and in time outgrows
The things that in our father's day were best."

THIS couplet is more than true, if it be applied to the street railway interests of Pittsburg, for in our own day and within a decade, things that were new have become old and have been replaced by better schemes, shaped out by men who have been made wiser by the rapid and steady growth of electrical truth. These men were so earnest they found no time to waste in patching; but have shoved aside the material and methods that were outgrown and that did not meet the demands of the time, and have reared a goodly work that is admirably suited to present requirements. The managers may well be envied by others who have not had the privilege of boldly shedding the old, and of putting on the new equipment. The scheme embraced the consolidation of all of the principal street railway lines of the city under the management of two companies, one known as The Consolidated, the other, The United Traction Co., with the mileage about equally divided and which embraces for each company territory in Pittsburg and Allegheny; the abandonment of cable power; and the re-equipment of all electric lines, and in the case of The Consolidated Company the power concentrated in a single station and central repair station. The same company has also six new modern power houses, and the manager has adopted a standard for cars, trucks, tracks and has grouped all the auxiliary appliances and details into units.

The Consolidated Company's new power station replaces the seven formerly required before the change from cable. The two storage battery stations, however, which were installed to help balance the power, will be retained. The location of the new station is on the bank of the Allegheny river, near Twentieth street, and not far from Penn avenue. The site is near the centre of the power distribution, making the average distance only about two miles, with a maximum of about seven miles. All the details of the power equipment, both electrical and mechanical, as well as the station, and in fact, all of the new structures, have been worked out by the chief engineer.

The power station is designed for an ultimate equipment of 20,000 h. p. The first equipment, however, consists of six direct coupled units. The engines are cross compound, condensing with cylinders 30 x 54 x 48, having Corliss valve gear, and there are several novel features in the construction of the cross-head, connecting rod, governing mechanism and other minor parts. The generators are each of 800 kilowatt capacity. There are twelve boilers of the water tube type, with a capacity of 4,500 h. p. The boiler room is parallel with the engine room, being separated by a fireproof wall, and the steam pipes drop down along the wall next the boilers and extend under the floor of the engine room to the cylinders, the throttle valves being controlled by hand wheels above the floor. An iron platform runs along the whole length of the wall of the boiler room on a level with the trunk steam pipe, from which the valves are readily operated. An electric traveling crane of 90,000 pounds capacity spans the engine room, providing for the quick handling of any piece of machinery. The building is of brick, the

front being of Pompeian fire brick, and the roof is supported with steel truss girders, while the covering is of concrete, felt and gravel. Large ventilating areas are provided, and these are shielded with stationary slats after the manner of Venetian blinds. The ground dimensions of the entire structure are 272 by 115 feet. The engine room is 55 feet wide, and the boiler house 60 feet, including a coal storage bin, which runs the whole length of the structure. There is also an elevated steel coal bin extending the entire length of the boiler room, which has a capacity for six tons per running foot, or a total capacity of 1,632 tons. A coal conveyor is provided, which is operated by an electric motor, by means of which coal is received from boats or cars at the river end of the building, and is by it placed in either of the storage vaults, or is taken from one to the other, as may be necessary, and by which the ashes are also removed. The condensers and auxiliary steam equipment are located in the basement, or rather in partitions, designed for them between the engine foundations, which are built up of concrete. The foundations for the structure and equipment are not less interesting than the superstructure, being all of concrete and built as a unit, while it rests on a foundation of river gravel. It contains 20,000 cubic yards of concrete, the side walls being in some places seven feet thick. The sand and the stone for the foundation were obtained from the river nearby, and were delivered by an incline to a large home-made concrete mixer, which has the capacity of 600 cubic yards a day; all the foundation work was put in by the company. The condensing water is lifted from a well 45 feet in depth, which is sunk below the low water mark of the river, the pump being about 17 feet below the coping, and is provided with an intake tunnel extending to near the middle of the river, and protected by a filtering crib.

The switchboard occupies a brick lined room in the foundation, and the switches are operated by air pressure from the engine room floor. From this the current is led out by lead-covered cables, through a brick tunnel extending to Penn avenue, a distance of nearly 600 feet. The interior of the tunnel is 5 by 7 feet, providing for an ultimate capacity of 40,000,000 circular mils of feed wire, while there is room left for the free passage of the employés. The foundation to this tunnel is of concrete, and in this is embedded in two layers thirty-two 63 pound girder rails, having their ends double bonded, and to which the return feeders are attached. At Penn and Liberty avenues the cables are brought up to the arms of a distributing pole from which they are led off in eight directions.

The new repair shop and auxiliary buildings are known as the Frankstown avenue car station, and comprise four large buildings, all of brick with a steel truss roof and of about the same general design. The three main buildings are all of the same width, and are placed in line with each other in the direction of their longest dimension, and between them are ample storage tracks, while they are connected by two tracks running the whole length of the plot, one outside the line of the building, the other within and next to the wall on the opposite side. The first, or operating house, is 135 by 220 feet and is constructed with a brick floor. The repair shop proper is 135 by 576 feet, and is divided into paint shop, wood shop, erecting department and iron tool department, with pits and dismantling devices with an electric transfer table in each department. The storage house is 135 by 400 feet, and between it and the machine shop is a large area for storage containing twelve tracks, which are connected by a diagonal cross track, having both single and double slips. The warehouse is located just outside the storage tracks, and is 50 by 150 feet. The power for driving the tools is derived from an electric motor, while some of the machines are provided with an independent motor. A special feature are the dismantling pits which are located in the main shop, and are each equipped with four sets of screw jacks, mechanically operated from shafts driven by an independent motor. With this equipment, the car body being run on and the body supported by proper bearings, a portion of the track with the truck is lowered when the truck is run to one side and another one substituted. This is then lifted in place, and the wiring connections are made, the entire operation requiring only about fifteen minutes. The inspection pits are conveniently located, and have no partitions between them, the rails being supported on posts, giving free access from one to the other, and an iron grating is provided, which answers for a floor between the different pit tracks. There is a wheel grinding machine of novel design with which the wheels are ground without removing

them from the car. A section of pit track is set apart for this purpose on which the car is run. The truck is then supported independently of the wheels, and a portion of the track under each wheel is removed. Centering lathe heads are provided on each side, and by removing the journal box covers the axles are readily centered and left free to rotate. The emery wheels are each operated by an independent motor, so that the speed can be regulated to suit the diameter, which varies as they are worn. These are so placed in the pit that they come in contact with the thread of the wheel on the under side, so the operation can be readily inspected, and being beneath the box, the dust cannot settle about the journal. The car wheels are revolved by their own motor in a direction opposite that of the emery wheel. To provide for proper resistance control under these conditions, a section of the trolley wire over the cars is partly cut out of the main circuit by means of resistance coils, which leave sufficient current to bring the car into position, while it provides for properly regulating the speed of the motor. An electric crane spans the main floor of the repair shop and provides for the prompt handling of car bodies, trucks or any heavy material.

The shops are provided with trolley hoists and all the labor saving devices which a long experience has proved to be desirable.

The buildings are warmed by a hot air system which includes a nest of steam pipes, with fan for forcing the air into the supply pipes. The storage house, which is also a receiving station, is provided with waiting and lunch rooms for use by the employés, and is equipped with 298 lockers, arranged in double-deck rows, each of which is ventilated and provided with hooks for clothing. In the receiver's office a marble slab is let into the counter at each window, which furnishes a smooth and durable surface, over which the envelopes and money are passed. The woodwork is of Georgia pine and finished and varnished in natural color. For ventilating the main floors, the deck lights on each side of the monitor roof are so arranged that for each section every other sash is attached to a sliding frame, which is provided with rollers and a track on which to run. By means of ropes that come down to the main floor, a whole section containing the alternate sash can be readily shifted, giving ventilation up to the full width of the sash.

The six new car houses are conveniently located in different parts of the city, and have the same general equipment. The one near Highland Park is built into the side of a bank, and one track is on the high ground, with a double track loop leading into the station, so that the trail cars can be dropped and run in by gravity. The front of the station is divided into waiting rooms, receiver's office, room for the trainmen, with lockers and tables and other suitable furniture. In the basement are toilet rooms for the employés, with wash basin and towels, the plumbing all being exposed, giving a very neat appearance. The finish of the office rooms is of yellow pine, and from the receiver's office a balcony opens out to the main floor, from which the foreman can count all the cars that may be in at any time. In the basement under the offices is located a supply room, boiler room and sand-drying apparatus. The building is heated by hot air, one of the old cable boilers furnishing the steam for heat, and for operating the fan of the heater. The telephone in the receiver's office is mounted on a hand elevator, so that it can be drawn and used by parties in the basement without the necessity of climbing the stair. The main building is of brick and corrugated iron, with a brick floor, the dimensions being 200 by 112 feet. There is track accommodation for thirty-four cars, while in front there are seventeen tracks, which occupy a large yard offering ample storage capacity. These tracks all connect with the main track, which forms the loop around the building. The house being designed only as a washing and inspection station, the cars when cleaned are run out and are held ready for service, an arrangement that saves the payment of insurance on the building. An electric transfer table operates through the middle of the floor, and on each side of the transfer track there is room for two cars to stand. The inspection pits occupy the space between the front and the transfer track, and these, like those in the machine shop, are not partitioned off from each other, but the tracks are supported on posts, while between the tracks an iron grating answers in place of the floor, which arrangement leaves but one floor to sweep, and prevents an accumulation of waste material.

As noted above, everything is standardized, and appliances

of the same kind are treated as a unit, repairs being made on a specified equipment at stated periods, without being left to wear out. The car trucks are of the McGuire type, the motors Westinghouse No. 38, and all the cars are provided with electric brakes of the G. E. type. The gongs are placed on the hood of the cars, and are rung by means of a cord that hangs just above the controller handle. This arrangement relieves the motorman from being obliged to stand most of the time on one foot, as when the gong is operated, as is usual by foot power, and also prevents the breaking of gongs, not one on the system having been broken for over two years. Moreover they do not sound as loud and offensive as when rung by foot.

Very few transfers are issued, as the routes are so arranged that they form concentric rings, coming to the same tangent point in near the centre of the city, and then spreading out balloon shape through the outlying territory. In answer to a question relating to the economy of the electric as compared to cable power on the lines which have been changed, the manager remarked, "that after the change the number of power plants was reduced from seven to four, sixteen boilers were sold, while a larger number of cars were operated," resulting evidently in a decided saving.

Trail cars are used on a number of lines, and all are equipped with the Van Dorn couplers for this purpose. These are so united as to leave no lost motion between the cars. On some of the trunk lines, the trail cars are dropped at the intersection of branch lines over which they are hauled by short independent motors. These dummy motors are entirely enclosed, and are provided with electric and wheel brakes, the latter being operated by a lever. By an arrangement of the trolley cord, the trolley pole can be manipulated by the motorman without leaving his cab. A continuous cord runs in both directions from the pole, passing down at each end of the car under a roller, and through from end to end under the ceiling. By this means the pole may be drawn down and freed from the wire by the motorman, reversed and returned to the wire ready for running in the opposite direction.

A new mail car of novel design, and which was built by the Laclede Car Co., of St. Louis, Mo., has recently been added to the equipment. This is provided with a stamp cancelling machine, which is operated by an electric motor. There are other labor saving arrangements which embody the latest practice adopted by the post office department.

The Consolidated Traction Company is operated under the management of C. L. Magee, president, and G. F. Greenwood, chief engineer and general manager.

Among the manufacturers and contractors for the new equipment mentioned above, the following may be noted: The Pennsylvania Iron Works Co., of Philadelphia, engines and auxiliary equipment; The Babcock & Wilcox Co., boilers; Westinghouse Electric & Mfg. Co., generators; Pawling & Harnischfeger, Milwaukee, electric traveling crane; Alfred F. Moore, Philadelphia, lead-covered cables; Jones & Laughlin, structural steel for roofs and coal bin.

The Henry "Regenerative" Controller For Electric Cars.

BY JOHN C. HENRY.

DURING the past year the writer has been engaged in the development of a new method of control for electric cars, which is named "The Regenerative System," a brief description of which was published last summer.

The system consists mainly of a combination of the features of the series multiple control, electric brake and independently excited motors. After making hundreds of tests, the great majority of which were failures, we have succeeded in producing a street car controller which has the following surprising advantages over the best of those in common use:

First—For all practical purposes we are able to increase the capacity of the present standard forms of motors about 25 per cent.

Second—In ordinary electric railway service an increased efficiency of 40 per cent. is within reach over the present methods.

Third—Much quicker acceleration is available than is possible with the ordinary railway motors.

Fourth—An ideal braking system is provided without friction or wear of parts.

Fifth—Without regulation the cars may make the same speed in the suburbs, where the voltage is low, as they do in the vicinity of the power station, thus avoiding the necessity for boosters.

Sixth—Arranging so that the cars run (without regulation) on the up or down grades at about the same speed as they do on the level.

Seventh—Arranging so that the motors are electrically tied together, thus preventing one of them from racing when they are connected in series.

Eighth—Reducing the output of the station and consequently the losses on the feeders and rails.

Ninth—Protecting the motor from injurious induced currents.

Tenth—Arranging so that the torque of or the ability of the motors to start or pull a very heavy load may be temporarily greatly increased without an injurious current in the armature.

Eleventh—Providing a braking system which cannot flatten the wheels.

For traction purposes an independently excited motor has about 25 per cent. greater capacity than a series motor of the same size and cost. To explain, it is well known the capacity of any form of motor is limited only by its ability to withstand heat. It is also well known that the heating effect in the conductors is proportional to the density of the currents. It is also well known that in order to secure light weight, compactness, etc., the efficiency of railway motors is not high when they are working hard or when they are overloaded. The field magnets absorb about 25 per cent. of the energy. Theoretically they should absorb none. What is needed is a magnetic abutment. It is not essential whether it be in the form of temporary or permanent magnets, providing it is strong and compact enough.

Our claims to improved efficiency will be readily appreciated in considering the following points. Tests made on the principal street and elevated railways in the country show that about 60 per cent. of the total energy used by the cars is absorbed in getting them under headway. The most popular controllers now in use have eight running positions, six of which waste energy by passing the entire current through dead resistance. With our controller we use no resistance in the armature circuits. Our regulation is done by the smaller member, that is, the fields which ordinarily handle but about 10 per cent. of the current, and at no time over 25 per cent. of it.

The other principal saving comes in by recouping current to the line. It takes nearly as much power to stop a car as it does to start it. In stopping, our motors automatically become dynamos and generate a current to the line, thus relieving the station dynamos, feeders, etc. The stored up energy of the momentum in the cars, or the force of gravity on descending grades is turned back into the line in the form of current. This is illustrated in a pretty way by placing a wattmeter in the motor circuit. Turning the controller handle on makes the disc revolve in one direction, showing it to be driven by current from the line, while turning it off reverses the direction of the disc, showing the current to be going back into the line from the motors. So sensitive is the wattmeter and this method of regulating motors that the disc will frequently change directions while running on level track without changing the controller. This action being caused by slight fluctuations in the line voltage.

High speed of the car is automatically maintained in the suburbs where the voltage is low. The explanation to this is that the strength of the fields is controlled by the line voltage. When it is low the weaker fields allow the armatures to take more current, and consequently they tend to run faster but with less torque. In consequence of these oppositional influences, the speed of the car remains about the same as when it is near the power station.

The greatest advantage of the system is in the ideal way in which it brakes the car without friction, avoiding flat wheels, etc. By simply turning the controller handle backwards the car is readily stopped, smoother even than with the air brake, or it is retarded on descending grades and any desired speed maintained by regulating the controller handle. The braking is all done by the armatures, without any additional mechanism.

On many roads rapid acceleration is desired. This is within easy reach with our form of control, and may be obtained in a much more economical way than is possible with series motors. In series motors heavy currents are necessary to speed up the armatures quickly, while these same heavy currents must pass through the fields which strengthen its magnetization and in turn

tend to retard the armatures. In the "regenerative" system each member is supplied with currents independently, so that the requirements for torque or speed may be met directly without waste. In the series motor the field magnets are not self-protected, while in the regenerative system the fields protect themselves automatically; that is, their current supply is controlled solely by their resistance. If they heat their resistance is increased and the current reduced.

While the same theory applies in series motors, with them it has but a small fraction of the force, as in the former the voltage across the fields is the maximum from the line, while in the series motor, in excessive cases, it would not be over one-quarter of this.

The most frequent cause of injury to motors is the "back kick," which occurs when the circuit is broken. This is generally the cause of grounding motors. Principally for this reason, shunt wound motors have not been used for traction purposes. There are two ways to avoid this danger. The first, to wind the magnets with heavy wire, which is not practicable. The second, to provide a better path for this discharge than through the insulation. To avoid this flash, and to protect our fields from this intense piercing stress, we place a non-inductive resistance of small carrying capacity within the controller, and arrange it so that it is connected in parallel with the fields whenever the armature circuit is opened independent of the fields. This same resistance may be used in special cases to protect the motors from lightning by using a supplementary switch.

When running with the motor in series with the "regenerative" system, the adhesion is greatly improved. The motors may be connected together so that any tendency of one of them to race is instantly and automatically checked by its current supply being decreased and that of its mate increased.

The series multiple method of controlling motors looks very simple, but it was canvassed over a long time before its success was assured. To change a pair of motors, which are using a heavy current from 250 volt to 500 volt machines in a fraction of a second without injurious arcing of the current or mechanical strains on the machine and car is the requirement. It was met first by Mr. Potter in a unique way; that is, by short-circuiting one of the motors. In doing this, the motor starts to act as a dynamo, and generates just sufficient current to counteract the residual magnetism in the magnets, which if it were allowed to remain would be sufficient to cause a tremendous current to be generated in the armatures. In changing the armatures in the "regenerative" system from series to parallel this same method could not be employed.

Instead, we short circuit one of the armatures with resistance, leaving the fields excited. The resistance is predetermined and arranged so that the armature, although revolving under strong fields, has its tendency to generate in the short circuit. Counteracted by the line current, which attempts to drive it as a motor, these neutralizing forces permit the armature circuit to be broken without any flashing. Another method of changing the armature from series to parallel is to break the circuit when the fields are weak and connect them in parallel under the fields when their strength has been doubled.

In the regenerative system, the reversing is done by the fields instead of the armature. Provision may be made within the reverse switch whereby putting the reverse handle in a second notch connects the fields from series to parallel thus providing for great torque or breaking force. This is operative only while the motor man has the reverse handle in the second position and is intended for use in emergencies only, such as starting heavy loads, pushing disabled cars up short, heavy grades, or for emergency braking stops to prevent accidents.

Ordinarily fields are wound so they would stand the full line potential all day without injury to the insulation. They consequently are much more reliable than those of series motors. The armatures when doing the same work carry 25 per cent. less current than if they were working as series machines. They are not exposed to the high induced current ordinarily projected by the field magnets when the circuit is broken in series machines, which is the common cause of disabling armatures, and they consequently will be more reliable.

With the regenerative system the car must be accelerated by moving the controller handle slowly instead of depending on the gradual automatic reduction of the field strength as in series motors. It is also very important that the controller be turned off slowly, because when the handle is back in the starting posi-

tion the car is at a stand. A quick sweep of the handle backward would make a stop too sudden for the passengers. It would send a tremendous current back into the line which would be liable to arc over at the motor's brushes and blow the fuse.

In the regenerative system arc extinguishing devices such as magnetic blowers, etc., are not necessary, owing to the small number of turns on the armature; the self induction and arc formed on breaking its circuit is very small as compared with that of series wound machines. In the regenerative system we break the armature circuit and maintain the fields at full strength, so that the back pressure is not reduced, and the difference of potential between the points of contact is but about 20 volts, as compared with 500 with the series motors.

When a reliable breaking system is arranged for within the controller, it leaves an opportunity for desirable improvements in car construction. The controller instead of occupying an unstable position at the car dash, where it is exposed to the storms, may be placed with its back against the end of the car body, under one of the windows between the steps and the car door. In this position, by using a specially arranged handle, the car may be operated from a position at the car door, either from the in, or outside, thus avoiding the necessity for vestibules, which are a necessity at some times, but generally a dangerous nuisance. This location is preferable, as the wires may be carried mainly under the car seats instead of exposing them underneath the car floor.

Newark, O. City Plant Mismanaged.

At Newark, O., on July 7, at the meeting of the City Council, a sensation was sprung by President D. L. Jones. He left the chair and called the attention of the body to the fact that the city electric light plant was being sadly mismanaged. The city, he said, was having the worst service in the history of the plant. Several men were employed therein, whose habits were so bad that for several days following each pay day they were incapacitated for good performance of their duties. Many lamps throughout the city gave no light because they were carelessly or improperly handled, and the time was not far distant when the city must incur a heavy expense to put the plant in good shape again. He offered a resolution, which prevailed, to have the light committee investigate the plant, with power to act. None of the employees were specified by name in the speeches of Mr. Jones and his colleagues. All would come under the investigation, though the head of the plant was recently made an elective office, and as such might be out of the reach of a Council committee.

PROF. SLABY has been appointed to a seat in the Upper House of Germany as a representative of the Charlottenburg Technical College, thus putting it on the same footing as the universities in Germany.

LIEUT. S. D. GREENE was on shore for a short time last week from the converted cruiser Yankee, and looked well after his busy West Indian cruise, though thin from constant work. In addition to incessant patrolling, the Yankee was in five different fights, in all of which her Naval Reserve boys distinguished themselves highly. As they say, "they took in Spanish washing" every Monday morning for five successive weeks and have now sailed, hoping for a continuance of that singular run of luck. Lieut. Barnard, an old electrical man, is also on the Yankee.

MR. LUTHER STIERINGER, the consulting electrical engineer of the Omaha Exposition, has gone off with Mr. Uhlrich, its landscape architect, on a trip through the Yellowstone Park region, to see whether nature can suggest any new effects to them.

Vol. XXVI. NEW YORK, JULY 21, 1898. No. 533.

Electric Power in Rolling Mills.

GRADUALLY but surely electricity is making headway in industries where other means of supplying power and light have heretofore reigned supreme. The iron industry in its various ramifications particularly has found in the electric current a powerful ally not only in the machine shop but in the rolling mill as well. What the current is accomplishing in that branch was very well brought out in a paper recently read before the Western Society of Engineers by Mr. Eugene B. Clark, of the Illinois Steel Company. As that gentleman showed, the conditions existing in a large rolling mill are particularly advantageous to the use of electric power for operating many of the auxiliary machines which are scattered through such a plant. Conceding that hydraulic and pneumatic transmission had each its own particular field in which it possessed special advantages, even when the field of each had been covered there still remained a large number of places to which power could be conveyed by electric means far more cheaply and conveniently than by any other method.

As to the question of "economy," Mr. Clark drew a distinction between the meaning of the word as viewed from the station manager's standpoint and that of the rolling mill superintendent. The item of convenience was oftentimes so important as to outweigh all other considerations. Mr. Clark then showed how motors of various types were applicable to the different classes of work in the rolling mill, such as the operation of cranes, hoists, conveyers, table rolls, transfer cars, charging and drawing machines, to all of which the series motor was peculiarly adapted. The shunt motor found its use in connection with lathes, shears, pumps, fans, grinding machines, crushers, etc. Then, again, there was the application of the current to lifting magnets, signals, testing devices, etc.

As to the lighting of rolling mills, Mr. Clark scored a good point for the enclosed arc lamp, which, he stated, possessed advantages even more marked than in the stores or halls, where they have superseded the open arc. It would appear that the trimming of an arc lamp in a rolling mill during a weekday nearly always interferes seriously with the operation of a part of the work being done there. Hence the long-burning enclosed lamp saves more money than is represented merely by the decreased cost of carbons, labor of trimming, etc. We dare say this experience will be noted in other industries as well, where continuous work is imperative.

As between the direct current motor and the alternating motor the author prefers the former for rolling mill work, for the present at least, on account of the difficulty of properly controlling alternating current motors in such work. Indeed, he asserted that the trouble at present was not with the direct current motor,

but with the controlling apparatus. Here is a hint which ought not to be lost on motor manufacturers. The intermittent nature of the power demand evidently makes the rolling mill a particularly favorable situation for the installation of storage batteries. Indeed, Mr. Clark proved by an analysis of his load diagrams that the installation of a suitable battery would permit of one 1,600 h. p. generator taking care of twice their present load, while at present it would require the operation of two such units. Taken altogether, Mr. Clark's paper makes an excellent showing for electricity in this particular field, but it is a repetition of the experience in so many other directions. In the present case it is only recently that rolling mill owners have realized the advantages of electricity, and it is safe to say that a not unimportant one among the causes that have led to the low price at which wrought iron and steel are now produced in the United States is the adoption of electric power in rolling mills.

Street Railway Travel.

A RESOLUTION is now before the New York City Council compelling the street car companies to provide each passenger with a seat, and to hang up a sign on the car when it is full. The proposer, Mr. Christman, says he acts in response to repeated demands from the public for regulations compelling the companies to do this. The proposition is a pretty one, and we have no objection to it except its utter impossibility. It would be a dead letter from the moment it was adopted, simply and solely because the public would not allow it to be enforced. One of the great trials of Americans in Europe, take Paris for example, is the fact that they must not get into a bus on which hangs the "Complet" sign, and that they therefore often have to waste hours and hours of valuable time, because the law does not allow them to travel standing up. Speaking for ourselves and from what we know of the public, we do not hesitate to say that people are far less anxious to get a seat than to reach their destination quickly. The recent resort to electricity on the New York street car lines shows this. Formerly on many of the horse car lines, though cars were few, there was never much trouble in getting a seat. Now that the cars have been electrically speeded up, and multiplied several hundred per cent., they always seem crowded. People are going to take this car and not the next, or the one after that. They will not loiter on corners. They will not stand out in the heat or the wet. They want to "go right along." Besides, on many lines, the management could not run more cars than they now do in the rush hours. Neither space nor speed permit. Sometimes, motormen after being stalled, and having their cars full, try to push past the impatient throngs at the crossings, and the keen disappointment shown at their action tells the whole story. The American public would much rather be crowded for space than for time.

This speedy travel, however, to which the trolley, overhead and underground, is accustoming the public, requires all the safeguards available to be thrown around it, and this is why we have always advocated the use of better and stronger brakes than the ordinary hand type. In Washington recently another of those "accidents" happened due to the inadequacy of the brake when the car was on an incline and nearly all the sixty passengers were badly injured. For that there is no excuse; and in fact in Utah, where a deaf and dumb boy was killed by a car with defective brakes, the court has held the company liable even if the boy were "negligent." In short, mechanical brakes of some kind or another, are a necessary adjunct of modern electrical street travel, and their adoption must soon become general.

Railway Motor Control.

THE experience gained in the construction of dynamo-electric machinery has now reached such a point of perfection that little more can be hoped for except in the way of details. This is true as well of motors as of dynamos. Indeed, as was remarked by a recent writer, it is not the motor but the method of and the apparatus for regulation that require attention far more than the machine regulated. This applies, we think, with full force, to the railway motor. As a mechanical device, the car motor leaves little to be desired. It had its infant troubles aplenty, but one no longer hears of cars laid up by the dozen for repairs, at least not in any well regulated railway company. But one may well ask whether the method of regulation now generally in vogue is the ne plus ultra. The series parallel system is no doubt a great advance on its predecessor, but even it

will be conceded to have its disadvantages, due principally to the employment of the series motor. This has been recognized and, as a matter of fact, shunt motors are in operation abroad at the present time, though to a limited extent. A modification of this latter type is now advocated by Mr. John C. Henry who, on another page, describes his so-called "regenerative" system of car motor regulation. By a method of separate field excitation Mr. Henry claims to overcome a number of difficulties met with in the series car motor; and if all the advantages pointed out can be realized in practice there is a large field open to the system. We must confess that we would like to see the records of current consumption on a large road equipped with the Henry system, for there is still a wide margin of efficiency to be striven for in railway motor operation.

Light Without Heat.

AN item from the London "Lancet" is going the rounds to the effect that the incandescent lamp, really, you know, when you come to look into the matter, gives off heat as well as light, and no small amount of heat either. "We have found by experiment," it says, "that on immersing a 16-candle power lamp (100 volts pressure) in half a pint of water, the water boils within an hour and in proportionately less time when a 32 candle power lamp is substituted. If again the lamp be buried in cotton wool, the wool soon begins to scorch and ultimately to burst into flame. In one experiment which we tried the bursting into flame of the wool was accompanied by a loud report, due to the explosion of the lamp. It clearly appears from this that the incandescent electric lamp cannot be regarded as an unlikely means of starting a serious fire, and shopkeepers, especially those who exhibit highly inflammable fabrics, should know that there is risk in placing such goods too close to the lamp. The lamp in contact with celluloid fires it in less than five minutes, and therefore the danger is particularly obvious in the case of toy shops, where electric incandescent lamps are often suspended in the midst of toy celluloid balls."

It is a well known fact that incandescent lamps are almost invariably burned, for illuminating purposes, immersed in a half pint of water, the water being intended to cool its fevered brow. When water is not used, it is the common practice to tie them up in cotton wool, as the "Lancet" intimates; and occasionally to swing celluloid balls in tempting dalliance around them in blindman's buff style. But, seriously, it seems to us rather late in the day to find out that it is difficult to get light without heat, or that there is a definite amount of heat from the various forms and mediums of illumination. The "Lancet" will in due time discover that electricity on the same principle of resistance in the circuit is now used for heating and cooking; and if its able editor will kindly call at The Engineer office, his contemporaries will be glad to give him a cup of 5 o'clock tea, boiled electrically. That, however, is no novelty in its way, and the "Lancet" could go back twenty years and find in print the facts it now parades as new with a warning to the ignorant. For ten years past, Tesla, Moore and many others have been trying hard to give us vacuum tube lighting, without resistance filaments, in order to get away from the only too-familiar facts of waste in heat in the incandescent lamp, which, after all, is and remains vastly superior in this respect and in various others to every competing method of illumination known commercially to mankind at this moment. Electricians will yet reach the approximate light without heat, but meantime under ordinary insurance regulations, the good old incandescent serves.

Building a Pacific Cable.

THIS country can never be a European power, but it is rapidly becoming a great Oriental power, and it is high time we built the Pacific cable about which there has been so much talk. Even if Spain should not wholly surrender her Pacific colonies now in making peace, she will have to let go sooner or later, and then we shall have to step in once again. The Sandwich Islands are ours by sheer weight and drift of events, and it is imperative for our future trade to keep "open doors" in the Far East, wherever possible, so that the hand of fate compels us also to insist on a prominent place in that part of the world, as owners if need be, but as rightfully there anyhow. We will go there peacefully if we can; but if we cannot, we will smash anything or anybody that gets in our way.

Such being the case, it is foolish any longer to be in touch with our dependencies and markets by the roundabout way of

Europe; and that Pacific cable landing on our Californian shore and running thence to Hawaii, Japan, the Philippines, China and Australia must be built forthwith. That is a large contract, but this country is equal to the outlay and as we have not yet got the construction and laying plant, our English friends will gladly welcome the opportunity to do the job for us, while their Government will lend all the aid it can, if only for selfish motives, and the more readily because our coming promises the success of that larger generous plan of commercial intercourse under which there is no discrimination. We are glad to note therefore that the executive council of the Hawaiian Government has granted to the Pacific Cable Co. the right to land a cable there which will connect with the U. S. A., China and Japan. All told, the company proposes to lay 12,345 miles of cable, and the Honolulu section is to be laid within a year from the time that Congress grants the proper authority, which, we imagine, will now be easily obtained, with the addition of a reasonable subsidy to be offset by the free transmission of governmental messages. The Pacific Cable Co., with a capital of \$10,000,000, and with such men as J. P. Morgan, J. K. Tod, J. A. Scrymser (of the Central and South American cables), Admiral Erwin and E. L. Baylis, ought to be quite competent to carry out its plans and purposes in good style, and should find an excellent return for its investment.

Independent Telephony in Indiana.

AN article has been contributed to the Fort Wayne "Gazette" by Mr. G. W. Beers, of that city, on the independent telephone movement in the State of Indiana. As is well known, that gentleman has been active in the campaign there, and he claims some decisive results for it. He says that instead of the 40 exchanges with 6,000 subscribers and practically no toll line service at the expiration of the main telephone patents, there are now 137 exchanges in the State with 20,000 subscribers and not less than 5,000 miles of intertown lines. This is but a beginning, however, for he adds that "this long distance movement is destined to occupy a position in the commercial life of the State excelled by no other interest." The truth thus set forth is incontestable, the growth of the toll lines being one of the most remarkable phenomena of present telephonic development, but beyond that lies the real long distance work of the Bell organization, which has already brought together the largest part of this country, and which so far remains without competition. In this respect, it is evident the Bell system retains enormous advantages over its competitors, making the proverbial "stern chase" a very interesting and protracted one.

How Best to Secure Exact X-Ray Indications.

HAVING read with considerable interest the description of the Fessenden X-ray apparatus in your last issue, I cannot but feel surprised at the fact that in this and many other recent articles in various electrical journals reference is made to the fact that photographs or radiographs are still being taken in connection with X-ray work, while it is a well-known fact that by the use of the fluorometer a great saving in time and tubes is effected, and much more accurate work done.

To properly locate a bullet in almost any portion of the body by photography requires the making of two radiographs; the work on which, including taking, developing, fixing and printing, takes fully two hours' time, and the surgeon has even then to probe for the bullet to a large extent by guesswork, guided, of course, by the two radiographs before him. Now not only does this process take up some two hours of valuable time, but the long exposure deteriorates to a great extent the tube which is used, so that the expense is great compared with the work accomplished. In using the fluorometer the patient is laid upon the table, the instruments are adjusted, the tube is turned on for a total of not more than five to ten minutes, and the patient's body is marked at four different points, which represent the terminals of two lines crossing each other at right angles at the intersection of which the bullet is absolutely sure to be found. In this case, as you will note, the marking is direct upon the

body and no error can possibly be made by the surgeon.

In view of these facts, it is almost impossible for me to conceive that any one could resort to the taking of a radiograph in the present advanced state of the art.

New York, July 13, 1898.

W. J. CLARKE.

"Citizen" and "Bell."

The Grand Rapids (Mich.) Press relates this incident about a man and a woman who are employed in different offices in one of the large buildings of that city. Each office has a telephone, but as it happens one is an instrument belonging to the Citizens' company, the other a Bell instrument. One day the man had occasion to use the Citizens' line and stepped across the hall to the lady's office. "Have you a Citizens' 'phone?" he asked, and she replied in the affirmative. "Well," he ventured, "I'm a citizen. May I use it?" Why, of course he might use it. An hour later she balanced the accounts with him. "Have you a Bell telephone?" she asked, on stepping into his office. He did not try to deny it. "Well, I'm a belle. May I use it?"

Recent Marconi Wireless Telegraphy in England.

JUST before last Christmas, the Wireless Telegraph & Signal Co. made a number of interesting tests with Marconi apparatus in the vicinity of the Isle of Wight, England, sending signals a distance of 18 miles. Since then they have established a station at Bournemouth, between 14 and 15 miles from Alum Bay, Isle of Wight, and between the two stations they keep up constant communication, with results already noted by the press. Lord Kelvin paid a visit recently to the experimental plant, when he examined the instruments carefully, and witnessed the sending and receiving of various messages. He sent dispatches wirelessly to Dr. MacLean, his chief assistant in the Physical Laboratory of the University of Glasgow; to Sir George Stokes at Cambridge; to Lord Rayleigh and Mr. W. H. Preece in London. The message to Sir George Stokes was as follows: "Stokes, Lansfield Cottage, Cambridge. This is sent commercially paid at Alum Bay for transmission through ether, one shilling, to Bournemouth, and thence by postal telegraph, fifteen pence, to Cambridge. Kelvin." Wishing to show his appreciation of the system and to illustrate its availability already for commercial use, Lord Kelvin insisted on paying a shilling per message royalty for the use of the Marconi system on all the messages he sent.

The system was also demonstrated recently before the British House of Commons, and the opportunity to inspect and investigate it has been freely afforded to scientists and others.

Telephony in Russia.

A report issued by the Russian postal and telegraph administration for the year 1897 contains some interesting information with regard to the present position of telephony in that country. The telephones are partly worked by the Bell Company and partly by the State, but it would appear that the former has managed to occupy the most remunerative areas, for while the number of subscribers to the two systems is nearly the same (11,171 and 10,419 respectively), the company works 11 districts in which are 15 exchanges, and the Government business is divided over 67 districts with 80 exchanges. The State owns 2,875 miles of lines, corresponding to 15,130 miles of conductor, and has 11,616 telephones in use. The length of the company's lines is 848 miles, and the length of conductor is 15,580 miles. The proportion of these figures is explained by the fact that the company's areas include the large towns of St. Petersburg, Moscow, Warsaw, Odessa, Riga and Lodz. Concessions for all but the last mentioned of these towns were granted in 1882, for Lodz in 1884. No new concessions have been granted by the Government since the year 1886, and on November 1, 1901, the State acquires the whole system.

When an electric tramway is started in a town the telephone

wires are altered to prevent disturbance in them, and the cost of this is charged to the tramway company. There are public pay stations in several towns, the charge for a three minutes' conversation being 11 cents for conversations with local subscribers, 23 cents through trunk lines up to a distance of about 33 miles, and 39 cents up to a distance of about 65 miles. The trunk lines between Odessa-Nikolaieff, Rostoff-Taganrog and St. Petersburg-Terrioki have produced a revenue of \$21,500. The work of erecting the trunk line from St. Petersburg to Moscow was resumed in the spring. The charge for a three minutes' conversation will be \$1.18, and a person will be allowed the immediate use of the line, out of his proper turn, for a triple fee.

Telephony Between St. Petersburg and Moscow.

The long-talked-of telephonic communication between the two Russian capitals, Moscow and St. Petersburg, is likely this year to become an accomplished fact. The line is under the control of the Imperial Telegraph Department, and the stations will be at the chief telegraph office in either city. As the average speed of ordinary telegraphic dispatches between Moscow and St. Petersburg, which are four hundred miles apart, is about that of the railway, ten or twelve hours being considered good time, the new telephone will prove an inestimable boon to business men, who in case of urgency are now obliged to pay three times the ordinary tariff to get their dispatches through as "special" messages. The line is not likely to be actually in working order before October.

Government Cable to Block Island, R. I.

A new Government cable has been laid between Block Island and Narragansett Pier. The cable was laid by order of Secretary of War Alger, and at Narragansett connects with the Providence Telephone Company's line, thus giving direct long-distance communication from Block Island to New York and Washington. While it will be open for public service primarily, it will be used for the Government signal service, and for the first time will establish direct connection with the signal service stations along that coast.

The Arc as a Telephone.

MR. H. T. SIMON, in writing to the "Wiedemann Annalen," No. 2, 1898, made the following interesting observations: If the circuit of an arc lamp happens to be close to another circuit traversed by feeble intermittent currents, the arc emits a loud rattling noise. The intermittent currents may be produced by a tuning fork interrupter, or by the hammer of a small induction coil. They produce in the arc circuit intermittent induced currents, and the latter affect the temperature of the arc and produce the noise. That the noise is due to the arc itself, and not to the regulating mechanism, is proved by the fact that the sound is heard equally clearly when the carbons are a fixed distance apart. Mr. Simon attempted to obtain a photographic record of the flickering of the arc, but failed because the changes of brightness are too slight in comparison with the total brightness. On placing a microphone in the primary circuit, the note of a tuning fork, and the sounds of whistling, tapping and singing were reproduced by the arc with every detail of intensity, pitch and quality. Experiments made with a shunt circuit showed that the quantity of electricity capable of producing an audible sound was 5×10^{-4} coulombs, corresponding to a change of temperature of 0.3° C. Sound waves acting upon the arc direct produced changes of density and fluctuations of the current, which could be transmitted to a distance and reproduced by a telephone at the other end.

Sender Must Stamp Telegrams.

Mr. N. B. Scott, Commissioner of Internal Revenue, has written a letter to the Western Union Telegraph Company, in which he says: "Upon the question as to whose duty it is to affix a stamp required by the act of June 13, 1898, to each telegraphic message offered for transmission, you are advised that this office rules that this duty devolves upon the person who makes, signs or issues the message."

Another Big African Telegraph Scheme.

KING LEOPOLD, of Belgium, has given Mr. Mohun, who was formerly United States Consul and Commercial Agent in the Congo Free State, and has since occupied a similar position in Zanzibar, a commission to build a line of telegraphs from a point about the middle of the west coast of Lake Tanganyika to Nyangwe on the Upper Congo, a town which was formerly famous as the headquarters of the Arab slave traders who had established themselves in the Upper Congo region. From Nyangwe Mr. Mohun is to carry a line along the river as far as Stanley Falls, where it will join the line connecting Stanley Falls with Boma and the lower river. From Stanley Falls the line is further to be carried along the Aruwimi, the river of which so much was heard during the Stanley Emin relief expedition, to Wadelai, in the valley of the Upper Nile. It will be seen that in this way two long arms will extend from Stanley Falls and join the great trunk line from south to north which Mr. Rhodes is pushing forward across Africa with so much energy. Mr. Mohun is allowed an entirely free hand in the selection of his staff, and English and American engineers will be employed. From Tanganyika to Nyangwe the forest trees are to be utilized, but along the banks of the Congo and the Aruwimi poles will be erected for carrying the wire.

Alternating Current Transformers—From the Station Manager's Viewpoint.¹—II.

BY W. F. WHITE.
(Concluded.)

IN another case one section of the city, comprising ten city blocks, was fed by one dynamo and a circuit through 71 transformers having an aggregate rated capacity of 4,482 lights, and aggregate core losses of 10,402 watts (estimated), or 91,121,520 watthours per year.

To replace these transformers, a three-wire secondary network was erected, supplying all customers, and fed by five 400-light transformers located at as many feeding points or local centres of distribution. Each transformer was provided with primary and secondary switches, by means of which each night all transformers were thrown into service from dusk until midnight, at which latter hour four transformers were cut absolutely out of circuit. On a yearly average, five transformers were in circuit about six hours per day, and one transformer the remaining eighteen hours per day. The combined core losses of the five were about 1,250 watts, and for the hours in service aggregated about 4,380,000 watt hours per year. Some results of the above changes on this one circuit, therefore, were as follows:

No. of Transformers.	Lights Capacity.	Total Core Losses—Watts.	Total Annual Core Losses, Watts.	Equivalent Tons Coal
71	4,482	10,402	91,121,520	446.7
5	2,000	1,250	4,380,000	21.5
Saving 2,482		9,152	86,741,520	425.2

A reduction of over 95 per cent. in core losses, and a saving for one year in cost of fuel alone of \$815.40 were effected for this one circuit. These examples were extremes, because the lighting covered by them was concentrated, and because in most residences and outlying business districts few changes in the number and capacity of transformers could be made. The results shown by the last example were therefore much above the average for the whole plant, but serve to show the possibilities of such changes and the methods pursued in this case.

Some results for the plant as a whole may therefore be fairly

indicative of what other average plants operating under similar conditions may accomplish in the same direction, and were as follows:

Time.	Lamps Connected.	Transformers Connected.	Total Capacity.	Average Lights Capacity.	Av. Lights Served.
Jan. 1, 1895.....	16,702	547	22,190	40.6	30.6
Jan. 1, 1896.....	19,282	201	13,865	69.0	90.1
Jan. 1, 1897.....	20,262	152	13,498	88.8	133.3
Jan. 1, 1898.....	23,643	141	14,946	106.0	167.7

It must be borne in mind that the number of 16 c. p. equivalents connected Jan. 1, 1895, was 16,702, and increased by Jan. 1, 1898, to 23,643, or more than 41.5 per cent. The savings estimated in the last table are based on the conditions at the beginning of this period, that is, the same number of transformers and the same transformer capacity. But if the same conditions had obtained throughout, an increase of 41.5 per cent., or 27 transformers, of 9,208 lights' capacity, would have been added to supply the new lights connected. And while only a part of the core losses of the transformers in service Jan. 1, 1895, was saved by the change, the entire losses of the 27 transformers, which would have been required by increased business, were saved. It is, therefore, perfectly safe to add 50 per cent. to the savings shown in the last table, in estimating actual benefits. From reduced core losses alone, therefore, an annual saving of approximately \$6,000.00 is being enjoyed.

In core losses alone, the savings already effected have more than paid all costs of the entire change of lamps, meters and transformers (for because of a simultaneous change from 52 volts to 106 volts, secondary, all lamps and meters also had to be changed), and of the erection of secondary networks, and the annual saving of \$6,000.00 is equal to 6 per cent. interest on \$100,000 secured without one dollar invested.

To be certain that the saving of fuel was in proportion to the reduction in kilowatt hours output, as estimated, the plant efficiency under the changed conditions must be known. It is, therefore, pleasing to note that, using coal from the same mine most of the time, the watt hours output per pound of coal actually increased for 1896 by 3.3 per cent and for 1897 by 5.9 per cent over 1895, so that the saving in fuel was at least not less than in proportion to the saving in kilowatt hours output.

Some incidental advantages of the change may be mentioned.

First—Under the old plan, the 6,941 lights added would have required about 9,200 lights additional transformer capacity, of 40 lights average size, of \$1 per light, average cost, giving an investment saving of \$9,200.

Second—The transformer load, with open secondaries, of 80 amperes, was reduced by the Fall of 1897, to about 30 amperes, notwithstanding an increase of about 25 per cent. in the number of lights connected. A saving of 50 amperes at 1,000 volts represents a capacity to serve, without additional station or line

¹Paper read at the general meeting of the A. I. E. E., Omaha, June, 1898.

equipment, approximately 1,000—16 c. p. equivalents, all burning at one time, or fully 2,000—16 c. p. equivalents connected.

Third—Formerly as many as a dozen transformers were frequently burned out in a single "thunder" storm. Ten per cent. of the transformers connected would be a conservative estimate of the number burned out each year from various causes. Of the new transformers connected during the past three years only one has failed from any cause, that one was defective, and burned out under light load almost immediately upon being put in service. Transformer repair costs are therefore practically eliminated.

Fourth—Incandescent lamp renewals have been greatly reduced. Using lamps from the same factory, of the same efficiency, and bought at the same price per lamp, the cost (estimated) of renewals per k. w. hour consumed by the lamps has been reduced from \$.0081 in 1895 to \$.0057 in 1897, a reduction of 29.6 per cent. This saving represents the advantage of regulating the secondary voltage by pressure wires connected to the secondary network, as compared with the former method of regulating the primary voltage by station transformers.

Fifth—The principal remaining incidental advantage is the uniformity of voltage, bringing uniformity in quality of service and consequent satisfaction of customers, the value of which cannot be estimated in dollars or percentages. These are some actual results and such as any plant operating under similar conditions can achieve at small expense, if the changes are well planned, and the replaced apparatus sold to the best advantage.

In this connection, attention must be called to one other fact, which is that central stations using separate transformers for individual customers have the great majority of their transformers working on open secondaries probably 80 per cent. of the time. The best transformers have a power factor of about 50 with open secondaries, and of fully 99.9 with almost any load they carry in practice. It is therefore perfectly credible, and the writer has demonstrated it to be so by many actual tests on various plants that the average power factor of plants operating under above specified conditions is approximately 65.

It scarcely needs demonstration that if, instead, a secondary network is used, and only such transformers allowed to remain in circuit at periods of light load as are required to advantageously carry such load, the average power factor will be approximately 100. The volt-ampere hours therefore, calculated from the station voltmeter and ammeter readings, give approximately the watt-hours output. But almost all existing plants use separate transformers for individual customers, and the great majority of them do not have primary wattmeters on their switchboards, and do calculate their volt-amperes-hours output as equivalent to watt hours, getting results about 50 degrees in excess of the facts. They therefore are able, apparently, to show 50 per cent. more watt hours per pound of coal, and 33⅓ per cent. less expense per k. w. hour output than another station operating under the same conditions and fully equaling theirs in actual performance, but which accepts the primary motor readings as the basis of estimate.

As a matter of fact, the usual disparagement is greater than the percentages given, because most station managers in erecting primary switchboard meters, follow their æsthetic inclinations, and use ornamental glass covers which are particularly susceptible to the admission of dust and grit, with the result that the meters rapidly slow down. It is highly probable therefore, that in some section the volt-ampere-hour record would show twice the number of apparent watt-hours per pound of coal and one-half expense per apparent k. w. hour output that would be shown by the record of the primary meter already erected on the switchboard, which tends only to show the worthlessness of the data from different plants, for purposes of comparison, unless the local conditions are known in each case.

This digression is permissible, we hope, because the average power factor, so far as we know, has never been taken into account, and because for that reason much misleading alternating central station data is in circulation.

Purchasers and users of transformers should insist that transformers meet certain requirements, or be rejected, and some of these requirements will be stated.

Where transformers are used for feeding networks, the secondaries in multiple, small core losses are of much greater importance than close regulation, and should be kept at the lowest practicable point. The regulation will be cared for by treating

the transformer and feeder drop together, through the use of secondary pressure wires.

Where the transformers are entirely independent, feeding separate secondaries, close regulation must be had and the core losses be made as low as the adopted regulations will permit. With constant full load the temperature must not rise to a high point, and should not exceed 50 degrees centigrade above the surrounding air. This is important not only because of the increased life of transformer insulation through low temperatures, but also, and possibly to a greater degree, because magnetic fatigue is a certain follower of high core temperatures. If, therefore, the core losses might be increased 50 per cent., or, possibly 100 per cent., through high temperatures, the cost of these core losses, as shown in the case of the plant above, makes argument unnecessary as to the desirability of having transformers run cool.

The transformer case should be filled with oil, because of its insulating qualities and its exclusion of air, and because of its assistance in maintaining the low temperature desired.

The insulation resistance between the primary and secondary windings should be able to stand up under not less than 10,000 volts, alternating, difference of potential, for transformers having 1,000-volt or 2,000-volt primaries, and the writer would strongly urge a 15,000 volts alternating test. If both the primary and secondary windings are on the core, the same insulation resistance should be required between either winding and the core, as between the two windings. The use of grounded shields placed between the primary and the secondary windings, the grounding of the shield or core, the grounding of the secondaries, the placing in each customer's service connections of any device to automatically open the circuit of such customer in case of an unusual difference of potential, are all practices that are opposed as expensive, as liable to cause, more than to prevent, trouble, as complicating existing practice, and as wholly unnecessary.

Proper insulation is sufficient protection against the damages sought to be avoided. Station managers as earnestly desire complete safety for life and property as the Underwriters' Association, but vigorously oppose the introduction of any unnecessary devices that are expensive to install and to maintain. That association, in seeking protection for the secondaries, should do so through sufficient transformer insulation and low temperatures. Both of these requirements mean increased cost of production and higher selling prices, but as the consequent increased economy makes the increased cost a profitable investment no reasonable manager will object. In this way the ends sought will be best attained, and the interests of all parties duly safeguarded.

Dielectric Strength of Air.¹

BY CHAS. P. STEINMETZ.

TO investigate the dielectric strength of air, tests were made of the striking distances in air between parallel cylinders of different diameters, between sharp points, and between spheres of different sizes. Further tests were made on the effect of inserting a conductor in or near the path of the disruptive discharge and investigating its influence on the striking distance.

As a source of power, an A-8 smooth core alternator of the Thomson-Houston type was used, of about 30 k. w. capacity and a frequency of 125 cycles, giving practically a sine wave. In other tests a 60 k. w. high-frequency ironclad alternator of the Thomson-Houston type was used, giving the well-known sawtooth form of wave. The alternator was driven by a direct current motor of ample capacity.

With alternating e. m. f.'s of only 125 cycles, the luminous phenomena, as brush discharges from conductors, etc., were much less marked and brilliant than observed even at lower voltages, with oscillating currents of very high frequency, as given by a Thomson transformer.

For the purpose of these tests four high-potential transformers were built, of the ratio of transformation 1 : 18 and of a rating of about 7.5 k. w. each. They are of the standard air-blast type, but were used when immersed in large wooden tanks filled with oil.

Each of these transformers contains two primary and two secondary coils, the two high-potential secondary coils in the center, the low-potential primary coils at the outside.

¹Abstract of a paper read at the 15th Annual Meeting of the A. I. E. E., Omaha, June, 1898.

Before undertaking the final tests, a number of preliminary tests were made to determine,

1. The constants of the generator and the transformers and the total power thus available in the discharge circuit.

2. The equality of the ratio of transformation of all four sets of transformers, since only at two out of the four transformers was the voltage measured.

3. The constancy of the ratio of transformation, since it was relied upon for determining the high potential voltage.

4. The shape of the generator wave and its variation under the conditions of tests.

The results of these preliminary observations are as follows:

Voltmeter readings on the low-potential side of the high-potential transformers give a striking voltage correct within one per cent., irrespective of the capacity of the discharge circuit, within the limits of the tests.

The wave of the smooth core alternator is practically a sine wave, and is not changed by transformation or by capacity of the discharge circuit.

Since the accuracy of the striking distance determination cannot well exceed one to two per cent., these preliminary tests show the method as correct within the errors of observation.

The author then describes a number of tests to determine the striking distance between parallel cylinders, giving the results in the form of tables and curves and observing that the striking distance increases faster than the voltage. A number of tests with spheres are also recorded with these results:

While the striking distances between spheres of different diameters are very different at intermediary voltages, they seem to coincide at very low and very high voltages, but differ essentially from the curve taken between sharp points, except at extremely high voltages.

From all these tests it should be expected that a law on the disruptive strength of air could be derived.

The disruptive electrical discharge bears a striking analogy to mechanical rupture. Thus, as the mechanical strength of a beam remains practically unimpaired up to a certain load, and at this load suddenly falls to zero by mechanical rupture, so the resistance of an air space is practically infinite up to a certain potential, at which, under disruptive discharge, it suddenly falls down to practically nothing. In looking for a physical law representing the electric disruptive discharge, it thus was to be investigated how far the laws of mechanical strength would represent the observed effects.

Under mechanical stress, rupture takes place as soon as the stress exceeds the breaking strain anywhere in the material, and this breaking strain is a constant of the material. Thus I investigated whether the disruptive discharge of air takes place as soon as the dielectric stress, that is the electrostatic gradient anywhere in the path of the discharge exceeds a certain constant value, which would be called the "dielectric strength of air" in analogy to the "mechanical strength" of a material. The mechanical strength of a material is tested by subjecting it to a uniform mechanical stress, the usual test of tensile strength by pulling a test piece of known cross-section to pieces. The analogous test of the dielectric strength of air would require a uniform electrostatic field, that is, parallel plates of perfect polish as electrodes. This is obviously not feasible. Thus I chose a shape of electrodes giving a relatively simple, although not uniform electrostatic field.

Between spheres, the lines of electrostatic force and equipotential surfaces are curves and surfaces of higher order. Between parallel cylinders, however, lines of force and equipotential lines are two linear systems of pencils of circles, or rather cylinders, that is, all lines of electrostatic force are circles intersecting each other in two points, the fundamental points of the pencil, and all equipotential lines are circles intersecting the first set at right angles, and containing the cross section of the cylinders as one pair.

Some further results on the question of the constant dielectric strength of air can be derived from the tests with points and with spheres as terminals.

Between mathematical points the dielectric field of force is similar regardless of the distance. Thus with the needle points used, for all distances great compared with the radius of curvature of the needle points, that is already the smallest distance investigated, the striking distance should be proportional to the voltage if it depends upon the maximum gradient. This, however, is not the case.

Between mathematical points even with the lowest voltage the gradient at the points is infinite. Thus with needle points very small voltages should strike over great distances. This is not the case either, but the curve of needle points does not differ much from that of $\frac{1}{4}$ " spheres. This leads us to one of the phenomena obscuring the true electrostatic gradient at the moment of disruption, the brush discharge.

Long before the disruptive voltage is reached between needle points and smaller spheres or cylinders, a brush discharge issues from the terminals into the surrounding air. The space surrounding the electrodes is filled with an infinite number of violet streamers issuing from the electrodes under a hissing noise and being constantly in motion, and this space is thus more or less broken down dielectrically, so that, when the final disruptive discharge takes place, the terminals of the discharge are no longer the original metal terminals, but the whole space covered by the brush discharge is more or less to be considered as discharge terminals.

To investigate whether the dielectric strength of air was reduced in fog, as occasionally suggested at that time, a steam pipe was arranged below the discharge circuit and steam made to escape very slowly, so as to fill the whole space between the needle points with dense fog. Against expectation it was found that a much higher voltage was required to strike across the same distance in fog as in dry air. From this it will be seen that fog increases in dielectric strength of air and reduces the striking distance very markedly. This may be explained by the assumption that the discharge is by the fog broken up in an infinite number of minute successive discharges, between the conducting fog particles, requiring a higher total voltage than the direct discharge over the same total distance.

By turning full steam on, issuing from the boiler at 80 pounds pressure into the space between the needle points, the striking distance was still reduced further below that in fog, that is, live steam at atmospheric pressure has a much greater dielectric strength than dry air.

From these tests, the following results are derived:

1. At constant voltage and constant wave shape, that is constant ratio between maximum and effective e. m. f., the striking distance is a constant, especially between sharp points, where the tests have been repeated over and over again, and independent of the atmospheric condition, the frequency, etc., to such an extent that the striking distance between needle points offers the most reliable means to determine very high voltages. For this reason, it is used in this manner as final check in all high potential insulation tests of the General Electric Company.

2. No physical law has been found to represent satisfactorily all the observations. Some point to the existence of a constant dielectric strength of air, analogous to the tensile strength of mechanics. Others point to the existence of a spurious counter e. m. f. of the spark or transition resistance from electrode to air.

3. Constant dielectric strength. Cylinders of 1.11" diameter give an average disruptive strength of air of 60 kilovolts per inch. Cylinders of .315" diameter, an average dielectric strength of 77. Spheres at very small distance point toward the latter value. As a disturbing factor in this case, enters the electrostatic brush discharge, which by a partial breakdown of the air surrounding the electrodes changes and increases the size and decreases the distance of the effective terminals.

4. Counter e. m. f. of the sparks. The tests with sharp points give 22 kilovolts, or 11 kilovolts for a single transition from terminal to air. Spheres give curves pointing to a similar phenomenon. Electric conductors inserted at right angles into or parallel with the discharge, point to the existence of a counter e. m. f. of the same magnitude. The beginning of the electrostatic brush discharge is at a potential of this magnitude also.

5. Potentials of 160,000 volts effective and even up to 170,000 volts have been experimented with. They are probably the highest voltages ever reached by man at ordinary frequencies with alternating currents of considerable power.

SAN FRANCISCO, CAL. The Pacific Coast Electrical Transmission Association held its annual meeting at the Cliff House on June 21, when an enjoyable and instructive time was had. The election resulted as follows: President, W. Frank Pierce, of the Blue Lakes Water Company; vice-president, Carol M. Beal, of the Power Development Company; secretary, George P. Low, editor of the Journal of Electricity; treasurer, William Angus, of the Stanford Electric Company.

Lightning Arresters.¹

BY A. J. WURTS.

IT is important in discussing a subject of this kind, which has been treated both in practice and in the laboratory, to establish the value of the laboratory experiments. The question is in experimenting with a static machine, are the experiments and deductions that we obtain there, fair in connection with lightning arresters which we use in our electric light plants? It seems to me that they are. The phenomena that we observe in the laboratory correspond with those which we obtain from a static discharge from our wires. In Fig. 1 I have drawn two straight lines, which may represent two perfectly straight wires, if you choose. In practice, during a thunder storm, that discharge does not occur from any one particular point. It will occur from this point or that point, according to certain conditions. Now, in the laboratory tests I have sent discharges into the upper wire there, called the A wire, and these discharges have to pass from the A wire to the B wire. The question is, where will that discharge occur. I have found that it may occur almost anywhere along the wire. Why is this? It seems to be because the static charge which is in the wire during a thunder storm surges back and forth on this wire in such a way that these waves collide with each other. To illustrate, take a trough of water and lift one end of it. Lower it and this water will surge back and forth in this trough. Now raise the end of that trough again and you get another set of waves. What will happen? Under certain circumstances the waves will collide, pile up and cause a splashing; under other circumstances, owing to

FIG. 1.

a balancing of the waves, a smooth place will be formed. That is what occurs in these wires. We have a splashing, and this static discharge tends to jump from the wire at these points where the splashing occurs. Now, it seems to me that these wires are charged by conduction from the atmosphere. Why? Because the wires become charged not only during thunder storms, but also during perfectly clear weather. The wire becomes a part of the electrically charged atmosphere, and, as I have explained, sparks tend to jump from the wire to the ground through any path that they can find.

Now, the point that I want to bring up, especially to the central station men here, is this: What is the easiest path for these discharges, and how shall we judge one kind of lightning arrester from another? In Fig. 2 I have shown a spark gap L and a resistance in series with that spark gap. In Fig. 3 I have shown three spark gaps without any resistance in series with them. The lightning arrester shown in Fig. 2 is a lightning arrester which is on the market now, and it is said of it that the insertion of this resistance decreases the necessity of spark gap; that is to say, by inserting a resistance we may use a smaller number of spark gaps than we could get along with without the resistance. Now, the question is which one of those paths will offer the least resistance to disruptive discharges. In determining the resistance of lightning arresters I have placed in shunt to any given lightning arrester, a variable spark gap, as shown in Fig. 4. Here a spark gap is shown with resistance in series, and in shunt to that arrangement I have placed a variable spark gap. Now, in the laboratory I have sent a disruptive discharge through that system from A to B. What path will that spark take—the lightning arrester or that variable spark gap in shunt to it? It will depend upon the length of the shunt spark gap, which I have called B' . If that B' spark gap is closed, the discharge will evidently take that path, and will avoid the lightning arrester, and by increasing the length of that shunt gap until the discharge will pass either through the arrester or through the shunt gap—by increasing the shunt gap until the spark will pass either one way or the other, we finally arrive at a point by which we can measure the resistance which the light-

ning arrester offers to the passage of disruptive discharges. The length of the spark gap which we obtain is the measure of the resistance of that lightning arrester. I have seen several statements in the papers to the effect that the lightning arrester should have a low breaking down e. m. f.; that is, you apply an e. m. f. to the terminals of your lightning arrester, and if the lightning arrester is to be connected to a 1,000 volt circuit the lightning arrester should break down at about 2,000 volts. Now, the lightning arrester, as a conductor of disruptive discharges, has nothing to do with the e. m. f. of the dynamo. As far as conducting the discharge away is concerned, if we apply

FIGS. 2 AND 3.

2,000 volts to that arrangement, shown in Fig. 2, the breaking down e. m. f. will be just the same, no matter what that resistance is. You can have, say 100 ohms in connection with that spark gap, or a million ohms, and it will not make a particle of difference about the breaking down e. m. f., but the resistance will make a great deal of difference as regards the lightning. That form has been called the short-gap lightning arrester. The resistance which is connected in series with the spark gap shown in Fig. 2 is said to be a low resistance. It is low compared with what? Lightning arresters, as ordinarily installed, are connected to the overhead wire and to the ground by means of fairly large copper wires of very low resistance, not more than an ohm or so at all events, and the joints are soldered. It seems to me very curious then that in such a path we should connect a resistance of quite a good many ohms. But by what right does anybody call that a low resistance? What is the standard? The only standard for the resistance of a lightning arrester is the ease with which it will conduct disruptive discharges to earth, with absolutely no reference to ohmic resistance or breaking down e. m. f. There is a great difference between the static discharge and the dynamo current. The dynamo current is more of a gentle force and can be likened to the force of wind moving water; the lightning discharge can only be likened to the blow of a hammer or the flight of a bullet. If we have a large pane of glass ordinary wind will not break it, but a bullet would find no difficulty in piercing that pane of glass. But it is an entirely different force that we are dealing with, and as I have described, the discharge is oscillatory,

FIG. 4.

swinging back and forth. Now then, suppose that we have a swing back and forth and in the path of that swing we have a pane of glass. That swing in its first motion will smash the glass and will then vibrate back and forth until it comes to rest without further resistance, disregarding the air and speaking only with reference to this pane of glass. Now then, in the place of the pane of glass, let us substitute a vessel of water, so that this swing that swings back and forth this way will have to pass through the water. The water is not removed and this swing has got to pass through the water and meet that resistance each time. Now, I liken that water to this non-inductive resistance in series with the spark gap and lightning arrester.

¹Abstract of a paper read before the N. E. L. A. Convention, June, 1898.

The discharge has to pass down through that resistance, up and down, up and down, each time, and the path with reference to the ease with which the discharge passes through it is hereby affected. But with the spark gap the air is smashed, the discharge bores a hole right through the air as a bolt does through jelly; the resistance is removed. The air has practically an infinite resistance as far as ohmic resistance is concerned, but this discharge bores a hole through the air and that stays there during those oscillations. That is the reason, in my mind, for saying that the equivalent spark gap, as shown in Fig. 2, is so much larger than the equivalent spark gap in Fig. 3, in spite of there being three gaps to one; so that the best path, in my judgment, for disruptive discharges is what I would call a free path, a path with any kind of resistance gap, not a restricted path, but a path which has nothing but a spark gap or several spark gaps I call a free path. The discharge will smash the air and form at once a free path for the oscillations.

University of Tennessee Record.

The May number of the above manual has just reached us, and contains, besides an address by President Dabney entitled, "The Making of a Perfect Man," an address by Dr. Mellen on "The Relation of the Public High School and the College," the academic announcement for the coming college year as well as numerous illustrations of college clubs and buildings. The course of electrical engineering, which is in charge of Prof. Perkins, appears to be very complete and practical, and entitles the graduate to the degree of B. S.

Purdue University.

The annual catalogue of Purdue University, which is located at Lafayette, Ind., has just been issued, and gives information on the splendid courses offered by this well-known university. The electrical engineering course in particular, which is in charge of Prof. W. E. Goldsborough, with a large corps of assistants, is splendidly conducted and in a practical manner fits the student for electrical engineering. Particular attention is given to the designing of electric machinery and appliances, and numerous electrical installations are inspected during the senior year. The curriculum includes in the senior year besides the ordinary courses taught in colleges, a thorough course in political economy, which appears to be a valuable acquisition for a technically trained man.

Michigan Engineers' Manual.

The Michigan Engineers' Manual for 1898, containing the proceedings of the Michigan Engineering Society, has some admirable papers which were read before the society at the annual convention at Port Huron, December, 1897. The papers are as follows: "Engineers' Personal Finances," "The Sewerage of Pontiac," "Curb and Sidewalk Grades," "The Horseless Carriage," "Electrolysis," "The Propeller Wheel," recent legal decisions and other papers of equal interest and importance.

University of Minnesota.

The bulletin of the University of Minnesota, located at Minneapolis, Minn., which is issued every six weeks, contains in its April 15th number the announcement of the College of Engineering and Mechanical Arts. The college appears to have a fine course in electrical engineering in charge of Prof. George D. Shepardson. It extends over a term of four years and is practical and thorough, as are all the courses offered by this university.

University of Vermont.

The bulletin of the engineering department of the University of Vermont contains very interesting information regarding this well-known old college and its excellent courses in engineering.

The electrical engineering course, which extends over four years, includes a large number of applied electrical subjects. The electrical engineering laboratories, which are illustrated in the bulletin, appear to be thoroughly and well equipped with all modern direct and alternating current apparatus, and the university has several well equipped and modern shops for the use of students.

Lehigh University.

The engineering department of the above university has just issued an interesting pamphlet containing a list of theses presented by candidates for engineering degrees. Among the electrical subjects are several of extreme interest to electrical engineers, about half of them being of the theoretical and the others of a strictly practical nature. It certainly speaks well for the high class of instruction furnished to the students of Lehigh by Dr. Macfarlane and his well-known corps of assistants.

Cornell University Physical Review.

Vol. vi., No. 5, of the Cornell University Physical Review, conducted by Prof. Nichols and Drs. Merritt and Bedell, contains among other interesting articles the following, which are of special interest to electrical engineers: "On the Surface Tension of Liquids Under the Influence of Electrostatic Induction," by S. J. Barnett; "On the Fall of Potential at the Surface of a Metal When Exposed to the Discharge Action of the X-Rays," by C. D. Child, and "An Instrumental Determination of the Period of Electrical Oscillation," by A. G. Webster.

Photograph of the Holy Shroud by Electric Light

IN Turin the other day, according to "Il Osservatore Romano," a photograph by electric light was taken of the Holy Shroud, which gave an admirable reproduction of the body of Christ. The Holy Shroud was recently exposed to veneration, and King Humbert, who is its hereditary guardian, at first hesitated to give authority to have it photographed, lest the photographs should be speculated in. However, his Majesty at length gave the requisite permission to Signor Secundo Pia, a lawyer and member of the Committee on Sacred Art, who had offered to photograph the Holy Shroud at his own expense. Signor Pia prepared his plates according to a special method, rendering them sensitive to the yellowish tint of the Holy Shroud by means of powerful electric reflectors. "Formerly," says "The Osservatore," "the appearance of the Holy Shroud gave an idea of the contour rather than the facial lineaments and body of Christ. On the other hand the photographs, on being developed, showed a perfect representation of the face, hands and limbs of Christ, the general effect being that of a photograph of Christ and not of his shroud."

Glass as a Conductor.

According to Maxwell's theory, ordinary conductors should be opaque to light. Electrolytic conductors do not come under this rule. If glass, therefore, is a conductor at high temperatures, the conduction must, as a first approximation, be regarded as electrolytic. A. Vosmaer, in "Electra," describes a striking experiment illustrating the conductivity of glass. Two electrodes terminating in glass rods are joined to the poles of a high-tension transformer. Nothing happens until the rods are heated by a Bunsen burner, when an arc is formed between them. The arc itself keeps the rods at conducting point, but as a rule the rods break, owing to some portion acquiring greater conductivity than the rest, and then taking all the current. If, before this happens, the electrodes are separated, a spark discharge sets in, and, on a further separation, a brush discharge. On bringing the electrodes together again the arc is re-established.

Testing Gold Quartz by the Röntgen Rays.

According to an English contemporary, an ingenious application of the Röntgen rays has recently been made, viz., to ascertain the presence of gold particles in quartz. The particles of gold in a paying gold quartz are often so finely divided as to be invisible to the naked eye. Since gold is much more opaque to the Röntgen rays than quartz, it is natural to suppose that some indication of the presence of gold in quartz would be given on the screen or the photographic plate when the quartz is traversed by the Röntgen rays. A physician in Los Angeles, California, is reported on accidentally photographing a lump of gold quartz to have found on the shadow of the outline of the quartz a number of very dark points. These points were due to the presence of particles of gold in the quartz. It is possible, therefore, to detect the presence of gold in quartz by the Röntgen rays, and it may sometimes be convenient in the laboratory, but it is not to be expected that the gold prospector will add a battery, an induction coil, and vacuum tubes to his rough and tumble kit for transportation over the Chilkoot Pass.

Nerve Currents.

F. Gotch and G. J. Burch in Proc. Roy. Soc., make a preliminary communication on the electrical response of nerve to a single stimulus, which they have investigated with the capillary electrometer. The form of stimulus employed was a relatively feeble induced current caused by the opening of the primary circuit of a standardized induction coil, which included one Daniell cell. The sciatic nerves of large frogs were used in all the experiments. The single stimulus was applied to the sciatic plexus 20mm. or 30mm. from the nearest of the electrometer contacts. The shock traveled along the nerve, past a pair of unpolarized electrodes joining the electrometer, and was followed by the nerve current in rapid succession. The exciting current also showed on the photographic record, but could be easily distinguished from the larger nerve current. The recording plate was attached to a pendulum motor, which also opened the primary circuit of the induction coil. Some of the nerves used were freshly prepared, other had been kept in the cold from 24 to 90 hours in 0.6 per cent. NaCl solution. The two sets of nerves showed marked differences. In the fresh nerve the first indications of the presence of the reaction occur 0.002 sec. after stimulation. The decline commences 0.001 sec. after that. In the kept nerve the loss of vitality is shown by a retardation both of the initial change and the rate of propagation. The latter falls from 10 or 15 to 6m. per second. When a certain length of the nerve is polarized by a slight constant e. m. f. the reaction differs according to the sign of the pole nearest the electrometer. The actual e. m. f. of the nerve current may be put as high as 0.032 volts. This fact is suggestive in view of the various theories of the electrical organ of fishes. It may be a nerve apparatus.

Telephones and Liquid Air.

Mr. Henry Norman, the well-known English journalist, in a recent article entitled "America Revisited in War Time," speaks as follows regarding the use of the telephone here and in England: "The observant visitor to America must be impressed first with the remarkable development of what may be called applied intelligence. Not only is there an extraordinary fertility of invention, but also, what is perhaps more striking still, there is apparently an instant readiness on everybody's part to make use of the things invented."

"From visit to visit, for example, I have observed a constant improvement in the telephone. The instrument has grown smaller, neater, more graceful, simpler and easier to use. As it stands on an American desk to-day it might by a flower-holder. In some of the best and most expensive parts of London to-day you cannot have a telephone put in your house at all. When you do, it is the ugly box arrangement of ten years ago. I called upon a journalist friend in New York. Upon his desk stands an elegant little apparatus, through which he converses every afternoon with Washington and Chicago. In a London newspaper office you might as well look for a machine for making liquid air."

Dr. Cornelius Herz.

THE death has been announced of this well-known man, who was at one time largely interested in electrical matters in this country and in Europe, and who sought shelter in England at the time of the Panama Canal scandal, with which his name was unpleasantly linked with that of Baron Reinach. Sir Edward J. Reed, in an article in the "Fortnightly Review" for January, 1897, said, in reference to Dr. Herz's case: "His vindication as a man of honor was bound to follow, and has now become an accepted fact in this country and elsewhere; the tribute of 'The Times,' of London, that 'Dr. Herz is a great man,' will be acquiesced in and endorsed throughout the world, and France, until she makes such amends as may be possible, must bear the reproaches of the civilized world. If a private citizen had inflicted such wrongs on Dr. Herz a court of justice would order a restitution of all extorted property, and would award him exemplary damages. Can a government, however mighty it may appear, be allowed to escape such a responsibility? It is to be hoped that Dr. Herz, if health permits and life lasts long enough, will endeavor to have this question answered."

Railway Motor Suspension.

The Walker Company has sent out a special circular, accompanied by a special letter from Vice-President Short, calling attention to a letter recently issued by President Coffin, of the General Electric Company, as to the Sprague motor suspension patent and the effect of the recent decision sustaining said patent. Prof. Short's letter and the circular traverse the statements made by President Coffin, and characterize them as "wilfully misleading," and the letter adds: "The motor suspension now used by the Walker Company is not the suspension that came to trial, and the statement made in the letter that 'practically every form of motor suspension now in use' is an infringement of patents controlled by the General Electric Company is erroneous." The Walker circular illustrates the difference by diagram and enumerates the points of dissimilarity.

Western Elec. Co. vs Am. Rheostat Co.—Motor Cut Out.

Judge Seaman, in the U. S. Circuit Court for the Eastern District of Wisconsin, has granted an injunction against the American Rheostat Company in favor of the Western Electric Company, suing under the U. S. Patent No. 565,867 of E. P. Warner, on a cut-out for electric motors. The defendants contended that the definition in claims 1, 2 and 3 as to the combination with a rheostat included in the armature circuit and provided with a contact arm adapted to be moved to cut in and out resistance, of a switch in the same circuit, independent of said contact arm, referred solely to the feature of the covering, which rendered the switch inaccessible to the operator. Barton & Brown and A. L. Lawrence appeared for complainant and Winkler, Flanders, Smith, Bottum & Vilas for defendants.

COLUMBUS, O., has become famous for its electric light arches across its High street. It was proposed to abandon them on account of the expense, but as the electric light company has reduced its price, the city authorities will stand part of the expense, and the merchants are willing to meet their part of the assessment. The arches are not only pretty to look upon, but have been a fine "ad" for the city itself.

Classified Digest of U. S. Electrical Patents Issued July 12, 1898.

Alarms and Signals:—

- AUTOMATIC FIRE EXTINGUISHING AND ALARM APPARATUS.** H. Eversmann, Cincinnati, O., 607,027. Filed Aug. 21, 1897. Designed to be used in connection with a pipe system which is normally empty and provided with a main supply valve which controls admission to the pipes accordingly.
- SWITCHBOARD FOR ALARM MECHANISM.** J. P. Conway, New York, 607,343. Filed May 5, 1897. Details of construction.
- ALARM SYSTEM.** C. Coleman, Chicago, Ill., 607,407. Filed Oct. 18, 1897. Means whereby localized portions of an electric protective circuit may be varied in character to prevent tampering with the circuit without sounding an alarm at the alarm station.
- ELECTRIC SIGNALING MECHANISM.** L. C. Rowand, Camden, N. J., 11,678, reissued. Filed December 15, 1897. Means whereby the repeating of a signal on the main line to branch lines is made positively automatic.

Batteries, Secondary:—

- ELECTRODE PLATE FOR ELECTRIC ACCUMULATORS.** P. F. Ribbe, Berlin, Germany, 607,078. Filed Jan. 25, 1898. Comprises a lead pipe, having openings, celluloid bars on each side of the plate, and connected together through the openings, the bars having undercut edges holding the active material.
- AUTOMATIC CUT-OUT FOR SECONDARY BATTERIES.** W. L. Negbaur, Brookline, Mass., 607,124. Filed Feb. 10, 1897. Comprises a magnet core provided with a non-polarized armature, a working circuit controlled by the armature, and two coils on the magnet core wound and connected to oppose each other, the armature being operated by the differential effect of the coils.

Conductors, Conduits and Insulators:—

- UNDERGROUND ELECTRIC CONDUIT.** T. Connelly, Chicago, Ill., 607,018. Filed Nov. 12, 1897. Composed of a series of tubes laid coaxially, the tubes being chamfered on their ends, and an unbroken, corrugated, metallic ring over the joints, for holding the tubes in line.
- ELECTRIC CABLE FOR DRIVING CONVEYANCES.** A. Norman, Toronto, Can., 607,070. Filed April 19, 1897. Consists of continuous positive and negative conductors, insulating material between and surrounding the conductors, and a switch for each conductor attached to and surrounding the cable.
- INSULATOR.** C. L. Wingard, Walla Walla, Washington, 607,315. Filed April 13, 1898. A tube divided into longitudinal sections, each of which has interlocking shoulders and a head at its outer end, so that the sections may be fitted together to form a continuous tube.

Dynamos and Motors:—

- ELECTRIC MOTOR.** W. S. Johnson and H. Winkenwerder, Milwaukee, Wis., 607,247. Filed Nov. 9, 1896. A simple compact motor for various kinds of light work that can be operated with a few cells of battery.

Measurement:—

- ELECTRIC METER.** W. D. Marks, Philadelphia, Pa., 607,185. Filed Nov. 4, 1897. An electric meter employing an ampere-indicator, a shaft, connections between the shaft and the indicator, and a supplemental pointer carried by the shaft.

Miscellaneous:—

- APPARATUS FOR MANUFACTURING OZONE.** E. Andreoli, London, Eng., 607,007. Filed Oct. 15, 1897. For description see page 539, issue of May 19, 1898.
- ELECTRICALLY HEATED ROLL.** F. P. Snow, Lynn, Mass., 607,093. Filed May 3, 1897. Consists of an annular core, wound with a primary conductor, and contained in a rotary shell, which forms the choking portion of a secondary circuit about the same core.
- ELECTRIC BREAK FOR INDUCTION COILS.** T. B. Kinraide, Boston, Mass., 607,176. Filed Feb. 28, 1897. A high speed break comprising a vibrating hammer, an anvil, a standard supporting the anvil, and a brace rigidly secured between the standard and the frame of the break.
- ELECTRIC BREAK AND INDUCTION APPARATUS.** T. B. Kinraide, Boston, Mass., 607,177. Filed July 26, 1897. Similar to above.
- ELECTRIC CURRENT CONTROLLER.** E. E. Werner, Philadelphia, Pa., 607,311. Filed Feb. 23, 1897. A measuring instrument used principally in cataphoresis or electromedical diffusion.

Railways and Appliances:—

- TROLLEY FOR THIRD RAIL.** L. M. Maxham, Boston, Mass., 607,065. Filed Sept. 1, 1897. Provides bearings for the trolley wheel adapted to resistingly permit a slight canting of the same, and means whereby such canting automatically guides the wheel toward the centre line of the third rail.
- TROLLEY.** W. H. Russell, Chicago, Ill., 607,194. Filed May 24, 1897. Details of construction.
- ELECTRIC RAILWAY.** W. W. Doty, New York; J. A. MacKnight, Mt. Vernon, and C. Grauten, New York, N. Y., 607,351. Filed Jan. 25, 1897. Sectional underground conduit system.
- TROLLEY FOR ELECTRIC RAILWAYS.** H. Van Hoevenbergh, New York, 607,387. Filed Aug. 31, 1897. Is provided with a plurality of wheels set at right angle to bear upon a supply conductor at their peripheries, the wheels being mounted in a frame provided with projections lying close to their sides to prevent spreading.
- ELECTRIC LOCOMOTION.** H. Van Hoevenbergh, New York, N. Y., 607,302. Filed Nov. 20, 1896. Employs an outgoing and return conductor adapted to be transversely by trolleys carried by a vehicle having electric motors but not traveling on rails.

Regulation:—

- METHOD OF AND APPARATUS FOR GENERATING ELECTRICITY.** W. L. Negbaur, Brookline, Mass., and J. J. Feely, Walpole, Mass., 607,125. Filed June 17, 1897. Provides a dynamo in connection with other means which controls the voltage of the whole system automatically without substantial change of its own voltage.

Switches, Cut-Outs, Etc.:—

- ELECTRIC CUT-OUT.** H. A. Lewis, Norristown, Pa., 607,250. Filed

July 14, 1897. Comprises a tube, a non-conducting rod held removably in the tube, a wire coiled on the rod, caps held in the ends of the rod, spring contact plates engaging the caps, and a circuit breaker operated by the expansion of the tube.

FUSE HOLDER, CIRCUIT BREAKER AND LIGHTNING ARRESTER. H. A. Lewis, Norristown, Pa., 607,251. Filed July 14, 1897. Details of construction.

Telegraphs:—

TELEGRAPH. L. W. Hildburgh, New York, 607,239. Filed June 2, 1897. Employs a main line and a source of alternating current therefor, and means for controlling the flow of the positive and negative impulses from the generator by short circuiting one set of impulses at the time of generation of either set of waves, the other set being unaffected.

Favorable Conditions.

An export trade that is just double the import trade must be a tolerably healthy basis on which to do business and accumulate money, and that is just what the U. S. A. did in the year ending June, 1898. Such conditions may not be readily repeated, but they bring encouragement and confidence, and there is no wonder that preparations for the Fall are reported to be on a large scale. Moreover, the victory of our army at Santiago has been no less decisive and convincing than that of the navy at the same place and at Manila, and it is now evident that the losses of the war will not be upon us, but that we shall secure a solid indemnity. All this makes for a strong market, and to it may be added the large gold finds now coming in from the Klondike. The Government bond issue is a great success, being subscribed five or six times over.

During the past week 11,498 shares of Western Union were sold, closing at 92¼, and 6,835 shares of General Electric, closing at 38¾, a decline from 40¼. In Boston American Bell Telephone sold at 275.

Copper, New York, sold at 11.65 cents, and heavy steel rail, Eastern mill, at \$17. The Third Avenue Railroad, New York, has received bids for 15,000 tons of rail and special work.

Sale of Brooklyn Edison Co., To Kings County Co.

Official announcement is made that George Foster Peabody, of the Board of Directors of the Edison Electric Illuminating Company, of Brooklyn, acting in concert with the officers, has closed a proposed sale of the stock of that company to the Kings County Electric Light and Power Company upon terms which the members of the Board of Directors unite in declaring to be for the permanent advantage of the company. This transaction is in behalf of the stockholding interests represented by the firm of Spencer, Trask & Co., and equally for all others. The deal will probably be consummated by October 1. The result to the stockholders will be in substance that the right to subscribe to 25 per cent. additional stock, at par, will be secured to them, and that for the whole amount of stock they will then be offered par in ninety-nine year 6 per cent. purchase money mortgage bonds, to be secured by the deposit of the Edison stock so sold, and additionally by a junior mortgage of the Kings County Company upon its property, and further by the deposit of a guarantee fund of \$1,000,000."

MR. D. McREYNOLDS has been appointed superintendent of construction of the South Texas district of the Southwestern Telephone and Telegraph Company, with headquarters at Austin, Tex. He moves from Houston.

CINCINNATI, O. The Edison Company's plant has had a bad fire, starting in the engine room and causing considerable damage, although the supply of current was maintained with creditable promptitude.

TRADE NOTES AND NOVELTIES

The Commercial Electric Co's. Iron Clad Motor.

WE illustrate herewith the new ironclad motor which has recently been brought out by the Commercial Electric Co., Indianapolis, Ind. They are built for two standard speeds and are intended for a variety of uses. In Figs. 1, 2 and 3 they are shown mounted on the ceiling. The magnet frame is of steel with circular cores and pole shoes of the same material, thus affording a low resistance air gap and the greatest possible efficiency of the magnetic circuit, while the end casings which carry the bearings are of cast-iron and are provided with ample ventilating holes. The workmanship and material throughout are of the highest class. The shafts are of steel and bearings self-oiling with bronze linings which are easily renewed. Carbon brush holders of simple construction and large capacity are used, and owing to the strong magnetic field sparking and

erators, 150 r. p. m., with a 9-section switchboard, for electrolytic service and the operation of two 75 k. w. 220-volt engine type generators, which will be used for lighting and power service. The installation will be the most complete of its kind in the world.

The Solar Carbon and Manufacturing Company, Pittsburgh.

IN the practical application of electricity for any purpose, carbon plays an important part. It is generally a factor in generating the current either by mechanical or chemical means, and is also a factor in its consumption or transformation, either for light, power, heat or for electrolytic purposes; and it is a curious fact, but not generally noted, that while the electric arc light has superseded petroleum oil to a large extent for illuminating purposes, the current cannot produce its light without burning a carbon pencil, which is usually made from a by-product produced in the process of refining this same petroleum oil. Consequently the manufacture of carbon, or rather the conversion of the crude material into special form for any purpose, is a comparatively new business, and gave rise in 1885 to the corporation named in this connection. The works of the Solar Carbon

FIGS. 1, 2 AND 3.—"COMMERCIAL" IRONCLAD MOTOR.

change of lead are avoided, so that the machines may run for a long time and require little attention.

They are thoroughly protected from mechanical injury, dust and dirt, while the large lids which are placed in the casing above and below the commutator allow of easy access to the brushes when desired. When suspended as shown in the cut, the operation of the belt tightening device is in no way interfered with or more inconvenient than when mounted on the floor, since there are no bolts to be loosened, but the machine can be mounted on its own support as with other ceiling machines. It is extremely convenient for direct belting to elevator machines when used in this way and the company makes a special reversible motor and controller for this purpose. The machine, it is needless to add, runs equally well if placed on the floor or regular foundation. The company will be glad to answer any inquiries on the subject.

Raritan Copper Works, Perth Amboy, N. J.

The development of electrolytic processes for the production of refined copper has proceeded very rapidly during the past three years, and at the present time a large proportion of all the refined copper is thus produced. The Westinghouse Electric and Manufacturing Company have installed a very large amount of apparatus for this class of service. One of the principal installations is at the refinery of the Anaconda (Mont.) Copper Company, where 10 generators of 270 to 300 kilowatts capacity have been installed. Another very large installation is that of the Boston and Montana Consolidated Copper and Silver Mining Company, Great Falls, Mont., where two 810 k. w. Westinghouse engine type generators are in service.

The latest comer in this field is the Raritan Copper Works of Perth Amboy, N. J., who are about to erect the largest copper refinery in the East. They have contracted with the Westinghouse Company for three 600 k. w. 150-volt engine type gen-

& Manufacturing Company are located at Mahoning, sixty-two miles up the Allegheny River from Pittsburgh, the location having been chosen because of its proximity to the natural gas fields, which at the time promised to furnish cheap fuel for the baking process, constituting the chief expense in the manufacture of finished carbon. In the manufacture of the various specialties turned out from these works, the process includes the grinding, bolting, mixing, moulding or forcing the plastic material into the required shapes, a process which was recently described in detail in these columns. The works of the company embrace six buildings, which are located on a tract of 100 acres. They are equipped with special machinery, and with calcining and baking furnaces, also of special construction. The equipment also includes engine power in two units for operating the same. The products embrace pencils, both solid and cored, for every known system of lighting; brushes for generators and motors, chemical battery cylinders of various forms, smelting rods, tubes, telephone parts and granules for telephone transmitters. The latter are made in four grades and of twenty-eight sizes. Among the specialties manufactured by this firm, are self-lubricating motor brushes, in which the lubricating feature is obtained without the use of graphite, the brush being pure carbon specially treated, which gives the desired results, and does not increase the resistance, as is the case with the graphite mixture. Another specialty, recently brought out, and in which the company controls the trade, are pencils of particularly fine grade, practically as smooth as graphite, and which are designed for use in the numerous chemical and refining plants that are springing up in the neighborhood of Niagara. The composition of these conductors is such that acids play no part in their destruction, consequently they have a life four or five times as long as some of the foreign made carbons, and are now even being exported for use in similar works abroad. Among the specialties that are remarkable chiefly because of their size, are smelting rods, some of which are solid cylinders 8 inches in diameter and 54

inches in length. The company do not, however, limit the forms or grade of their products to catalogue lists, but are always ready to design moulds or dies for any special forms that may be required. They will make anything that can be made from carbon, except diamonds of course, but they will probably make them as soon as anybody else. The products of the concern go to all parts of the world where electricity is used as an applied art, and are claimed to compete favorably with the best of foreign products in any line. The city office of the company is at 339 Fifth avenue, and the practical management of the business is in the hands of F. B. Laughlin, general manager, and his son, F. M. Laughlin, treasurer.

Repairing a Railway Generator Armature, Cleveland, O.

THE illustration herewith shows the power station on Cedar avenue, of the Cleveland Electric Railway Co., and the process of rewinding one of their 500 kilowatt generators by the W. H. Elliott Electric Co. of Marine Block, that city. The generator is the third that has thus been wound for the Railway Company this year by the Elliott Co., who do all their generator repair work, and who have exceptional facilities for handling heavy electrical jobs of that character. Their trade extends from Oregon to Florida, as they have just shipped two large armatures to the Salem, Ore., Consolidated Co., and have also done some work for Jacksonville, Fla.; while they are also busy on local work, including an M. P. 100 for the New York & Ohio Co., of Warren, O.

The business of the W. H. Elliott Co. is that of rewinding

500 K. W., G. E. MOTOR BEING WOUND BY THE W. H. ELLIOTT ELECTRIC CO., FOR THE CLEVELAND, O., ELECTRIC RAILWAY CO.

armatures, fields, transformers, etc., refilling commutators and making new ones; building new armatures, etc., for all classes of electrical machines, and doing experimental work. They are at present running day and night shifts, and expect to do so for some weeks to come on the orders now in hand. Mr. Cartwright, the president of the concern and its manager, was one of the two men who started what is said to be the first dynamo and motor repair works in the United States, giving its entire attention to that class of work. From that time—June, 1887—to the present, he has devoted his time and energies in the same direction, and the result is seen in the successful work and continuously growing patronage. Mr. Hankey, the secretary and treasurer, who has charge of the clerical force, is a new man in the electrical field, but is rapidly making a large circle of friends and acquaintances.

The "Monarc" Enclosed Arc Lamp.

The firm of Albert and J. M. Anderson, of 289 A street, South Boston, Mass., have brought out a number of valuable lines of apparatus in the electric railway and other special fields, and are now introducing another novelty in their "Monarc" enclosed arc lamp, which is shown herewith. The lamp is only 22 inches over all, and burns carbons $\frac{1}{2}$ inch by 12 inches. The standard lamps of this style require $4\frac{3}{4}$ amperes, but can be furnished to take 3 or 4 amperes if so desired. There are a number of interesting and novel features, all intended to make the lamp economical and efficient. The work of trimming has been made very easy, there is good contact for the carbon, and the best shape for the inner globe has been determined after many experiments on light, and with a view to the minimization of breakage. The magnets and all other parts of the lamp are easily removed and replaced, and all mechanical details have been worked out with great care and attention. The "Monarc" lamp is furnished with alabaster inner and clear outer globes, unless otherwise ordered. It is rated to burn for 150 hours on one trimming. Class A lamps are designed for 110 volt circuits with a range from 105 to 118 volts, and with $6\frac{1}{2}$ ohms resistance to each lamp. Class B lamps are designed for multiple series lighting on street car circuits, ranging from 200 to 1,000 volts, $6\frac{1}{2}$ ohms resistance per lamp. The firm are now pushing this lamp actively and will be pleased to receive inquiries and orders.

Improved Holtzer-Cabot Automatic Burner.

THE Holtzer-Cabot Electric Company, Brookline, Mass., have recently made a neat improvement in their well-known automatic gas burner. This consists of the addition of extended pole pieces or shoes which reach down almost to the outer edge

IMPROVED HOLTZER-CABOT AUTOMATIC BURNER.

of the armature, extending the magnetic field and making it more effective. It will be observed that a stronger action is now obtained, even with less battery, than was formerly required, as the air-gap between the armature and fields has been almost closed.

Extensive Additions to Walker Company's Plant.

The Walker Company, on account of rush of work and consequent need of additional space, has found it necessary to add to the large machine shops it already possesses at the Cleveland works. These machine shops alone consist of three bays, each 400 feet long, and the addition will consist of a fourth bay. Work is being rapidly pushed, and the new bay will be shortly completed and ready to receive the large machine tools which are to be placed there.

G. E. Compensator for Series Incandescents.

ONE of the great obstacles with which the series system of incandescent lighting has had to contend has been its want of flexibility. If the circuit is laid out for the full number of lamps which the normal voltage will operate, a means must be provided for increasing the voltage to take care of additional lamps ordinarily called for for a short time. On the other hand, if only a part of the possible number of lamps are connected in circuit, expensive or complicated arrangements are necessary to absorb the surplus voltage.

For satisfactorily controlling the voltage, the General Electric Company has developed a form of potential regulator especially adapted for this work, by the use of which the series system becomes almost as flexible as a parallel system, and the power consumed in the circuit varies directly in proportion to the number of lamps in use. A regulator panel, with ammeter, switch and fuses, is shown in the illustration. The regulator is mounted on the back of the panel and consists of a compensator, from the secondary winding of which taps are connected to a set of contact blocks arranged in circular form on the front of the board. A hand wheel in the centre of the ring of contacts operates two arms carrying brushes which connect from the contact blocks to continuous rings on the inside and outside of the contact blocks. One of these arms is connected directly to the hand

G. E. COMPENSATOR FOR SERIES INCANDESCENTS.

wheel, the other is connected through a bevel gear, so that the direction of rotation of one arm corresponds to that of the hand wheel, while the other moves in the opposite direction.

The compensator is so connected that whatever difference of voltage exists between the two concentric rings on the dial switch is added to or subtracted from the initial voltage of the circuit. If one arm be directly over the other, there is no difference of potential between these rings. If the hand wheel be turned to the left a gradually increasing voltage which will be added to that of the line will be developed between the rings, while a gradually increasing voltage, which will be subtracted from the initial voltage, will be developed if the hand wheel be turned to the right. The ammeter below the hand wheel indicates the current in the circuit. When the number of lamps in circuit is changed it is simply necessary to turn the hand wheel until the proper current is indicated.

The compensators are wound for the standard currents of 3, 5 and 5.5 amperes, and in either case will increase or decrease

the initial voltage of 1,150 or 2,300 by 230 volts. Special regulators giving a greater range of voltage will be built if desired.

Kent Battery Fan Motor.

Kent Battery Fan Motor.

A CONCERN which has enjoyed considerable success with its fan motors is the Kent Electric Manufacturing Co., of Worcester, Mass., which is still extending its line of specialties and novelties. It has now brought out a new battery fan corresponding to its Type C of last year and intended specially for battery work. It is well shown in the accompanying cut, and is evidently a strong, compact little machine. It carries a 10-inch fan, and the finish is black enamel, with nickel trimmings. The one bearing is 3 inches long and is part of the field magnet frame at the neutral point, so that there is no bother with bearings to adjust and the shaft does not bind or get out of alignment. Moreover, as there is no bearing at the commutator end, that important part of the motor has no likelihood of being clogged or partially insulated by trickling oil. The armature is of the Kent drum type, such as has been in use now for two years, and it runs with great smoothness, quiet and efficiency. The binding posts for the attachment of the battery wires are placed, as will be noted, in a convenient position alongside the field coil. The Kent Company is doing well with this motor and will be glad to receive correspondence and inquiries in regard to it.

Manufacturers' Building, Providence.

One of the largest and best equipped power buildings in the United States is the Manufacturers' Building, Providence, R. I. This building has accommodations for upwards of sixty manufacturing concerns, being particularly equipped with conveniences for the production of jewelry, specialties, etc. The Manufacturers' Building Company have just purchased a 250 k. w., 500 volt Westinghouse engine type generator, 100 r. p. m., to be driven by an Armington & Sims Corliss engine. This generator will supply power for the operation of motors in the various manufacturing departments of the building. The engineering features of this establishment are under the direction of Lewis & Claffin, consulting engineers, whose wide reputation for engineering installations of the highest order is borne out by their selection in this instance.

Pelton Water Wheels.

The Pelton Water Wheel Company, of San Francisco, Cal., report a very active business at both their San Francisco and New York works. The war has affected to some extent their export trade, still this on the whole is very satisfactory. Electric power transmission plants are still a prominent feature in the work of this company. Among their more recent contracts are the following: A 1,200 h. p. plant to operate the Odawara Electric Railway in Japan, wheels to run under 400 feet head; 650 h. p. plant to operate a cotton factory in Japan; 500 h. p. wheel for the Blue Lakes Electric Power Plant in California; 800 h. p. plant for the Auburn station of the Central California Power Company; 1,500 h. p. plant for the Tuolumne Electric Power Company, California; 750 h. p. plant for the Griffith mine, Tuolumne county, California; 250 h. p. plant for the Ventura Electric Light and Power Company, Cal.; 1,200 h. p. plant for a railway company in British Columbia; 250 h. p. plant for the Salt Lake & Ogden Railway Company; 300 h. p. plant for the Farfan Electric Power Company in Peru; 7 wheels for the California Powder Works, Santa Cruz, Cal.; 4 wheels for air compressor plants in Alaska; 2 wheels for various mining companies in Alaska and British Columbia; 3 wheels for Central America; 7 wheels for various mining purposes in Mexico; 13 wheels for various mining purposes in Utah, Montana and Idaho.

THE BALL ENGINE CO., Erie, Pa., have recently received orders for several engines from Mexico.

The Campbell & Zell Company, Baltimore.

THIS company are closely allied to the electric industries of Baltimore in that they have built the boilers for all but two of the street railway and electric light power stations. They have also supplied the boilers for twenty-five or more railway power and electric light stations in different parts of the country. The special type of boiler adapted to this particular service is known as the Zell improved water tube safety boiler, which is manufactured by the above company at their extensive boiler and marine works located at the foot of Wolfe street, Baltimore, occupying the whole of a large sized city block, having a water front of about 1,500 feet. These shops are equipped with the latest improved machinery, and the business of the company is not limited to the manufacture of the Zell boiler, but they turn out high grade tubular boilers, Scotch marine boilers, marine engines, propeller wheels, stacks, steel tanks of every description and various other work of a similar character. The foundry of this company is located a few blocks from the main works, and is one of the largest and most complete in the South, being also equipped with modern tools and having a large pattern shop, the company doing a large business in light and heavy gray iron castings.

Regarding the features of the construction of the boiler, it rests on two saddles placed under the mud drum at the rear lower end, and on a roller carried by the arch plate over the fire doors at the front end, thus relieving the nipples joints from the weight of iron and water which intensifies the action due to the alternate expansion and contraction of the parts.

The water drums are placed parallel to the incline of the water tubes, and the feed water is introduced at the rear lower end of the drum, from which point it naturally descends into the rear headers to be distributed among the tubes. The greater part of the impurities will naturally be precipitated at once from the feed water on its contact with the hot water in the boiler, and will collect in the mud drum below; and the remainder is deposited there by the succeeding passages of the water through the rear headers, due to a rapid and free circulation.

The sections are made up with rhomboid headers at the ends, each containing four tubes, and the hand hole plates covering the tubes are placed on the inside, thereby having the steam pressure holding the joints tight at all times. These joints are milled on the inside, and the hand hole plates are milled off, making a perfect joint. One of the main features of the Zell boiler is the superheating arrangement consisting of separate drum and superheating tubes. These tubes are composed of the best quality lap-welded wrought iron and extend from the manifold to the steam drum in the rear. They are placed in a single row, and are expanded at their ends into both the manifold and steam drums. The steam, after disengaging itself from the upper end of the water drum, passes into the superheating tubes, where any entrained water is evaporated, from thence into the steam drum. The drum is exposed to the hot blast about three-fifths of its own circumference, thus insuring perfectly dry, superheated steam.

Ohio Electric Specialty Co.

The above concern, of Troy, O., who have long made a specialty of dynamo and motor brushes, write us that the Perfection brush manufactured by them is the result of the ideas of inventors and designers now associated with them, and they trust that "all cheap imitations of this type of brush placed on the market by parties claiming to be the designers will be spurned by all intending purchasers." Mr. J. R. Simpson, of the Ohio company, says that they make a point of not sacrificing quality for price and that all their improvements are made available to customers as quickly as possible and as circumstances demand. Their woven wire brushes are well known to the trade and have secured on their merits a position which Mr. Simpson hopes and expects to maintain.

MR. H. A. WAGNER, of the St. Louis, (Mo.) Edison Company, has been an Eastern visitor the past fortnight, staying at Asbury Park and transacting a large amount of business between whites.

THE WESTERN ELECTRIC COMPANY recently mailed to the trade copies of its tool catalogue No. 3. If any reader of The Electrical Engineer failed to receive a copy, one will be sent upon application.

Stone & Webster.

Only a few weeks ago we had occasion to call attention to a very instructive power station test report issued by the above firm, and we are just in receipt of another very interesting production of these enterprising engineers. It consists of a little cloth-covered book containing, besides a long list of properties examined and reported upon by Stone & Webster, several tables of Boston and Massachusetts street railways, accompanied by valuable statistics. These tables will be of special interest to investors and street railway men, and will be sent to anyone on application to Messrs. Stone & Webster, 4 Postoffice Square, Boston, Mass.

The Electric Storage Battery Co.

Circular No. 41, entitled "The Installation of Chloride Accumulators in the Waldorf-Astoria Hotel, New York," has just been issued by the Electric Storage Battery Company, of Philadelphia, Pa. It is illustrated by large half-tone cuts of the hotel, some of the cells as they appear in the battery room, ammeter charts illustrating the method in which the battery performs its functions as a regulator, the large, handsome switchboard installed and the 20 k. w. motor-driven differential booster. The pamphlet is a useful one, and aptly illustrates the application of storage batteries to isolated plants.

Ball Automatic Cut-off Engines.

ONE of the handsomest engine catalogues ever received by us is the latest issued by the Ball Engine Company, of Erie, Pa. Within a handsome cover, ornamented by numerous incandescent lamps and an embossed likeness of Hero of Alexandria's engine, we find a volume of valuable information on engines for electric lighting, electric railways and general manufacturing plants. The catalogue contains beautiful half-tone illustrations of the company's factories, their awards, direct connected engines, the single cylinder, centre crank railway engine, portions and sections of the various Ball engines, the single cylinder engine, the cross compound engine, as well as the well-known tandem compound and vertical cross compound engines. All this is accompanied by interesting descriptive matter and essays on electric lighting, electric railways and mining, factory and mill service, etc. In the back of this very handsome catalogue, which is a model of modern typographical excellence, are complete tables of the numerous styles of engines manufactured by the Ball Company. The catalogue is called H, 1898, and will be mailed to anyone on application.

Edison Mfg. Co.

A neat and dignified catalogue in handsome red cover has just been issued by the Edison Manufacturing Company from its new headquarters in the St. James Building, Broadway, this city. It is a pamphlet of 68 pages, and its text and cuts are up to date as to all the latest developments and apparatus of this progressive concern. We note a variety of fine Röntgen-ray apparatus and the new line of electro-therapeutic specialties, all of which are well illustrated and described, including the beautiful Edison sinusoidal alternator for medical use, the Edison-Heiman electrical centrifuge, etc., the new combination cabinets, etc.

SUPT. ALDRIDGE, of the State Department of Public Works, has written to the E. G. Bernard Co. a warm letter of commendation on their recent wiring work at the Capitol at Albany, noted in our columns last week. He is evidently much impressed with the skill and energy displayed by this enterprising concern.

CENTRAL ELECTRIC COMPANY, of Chicago, are carrying in stock large quantities of wooden and iron pins and brackets, and glass insulators. They have considerably augmented their previously large stocks and are prepared to take orders of any size.

ADVERTISERS' HINTS

THE RELIABLE ELECTRIC MANUFACTURING CO., 86 Foster street, Worcester, Mass., call attention to their complete line of telephone instruments, apparatus, etc. They guarantee all they ship.

THE ELECTRIC GAS LIGHTING COMPANY, 192 Devonshire street, Boston, Mass., advertise annunciators of the finest quality and the lowest price.

THE DEARBORN DRUG AND CHEMICAL WORKS, Chicago, have over 15,000 analyses of boiler water on file. Their method is to prescribe a special compound to suit each individual case.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, are now issuing their general catalogue No. 12. It is to be had for the asking by anyone in the trade.

THE AMERICAN IMPULSE WHEEL COMPANY, 120 Liberty street, New York, say the Cazin water wheel is giving satisfaction wherever used for power transmission and the hundred other uses to which it can be put in large and small units.

THE ELECTRICAL ENGINEER INSTITUTE OF CORRESPONDENCE INSTRUCTION, 120 Liberty street, New York, continues the publication of valuable data in its "ads." Many of these tables have never been compiled before, and they are well worth preserving.

WESTERN NOTES

M. C. BULLOCK MANUFACTURING COMPANY, of Chicago, as manufacturers of the Bullock-Willans central valve engine, request us to call attention to the fact that such is the engine's full designation. In our issue of July 7 we illustrated and described it under the name of the "Bullock central valve engine," and the company are desirous that the proper designation shall be the one by which it is familiarly known to the public.

THE ADAMS BAGNALL ELECTRIC COMPANY, of Grand Rapids, Mich., has been formed, with a capital stock of \$225,000.

THE COLBY ELECTRICAL MANUFACTURING COMPANY, of Chicago, has certified to a change of name, which certified to a change of name to the Wells Goodhue Company. Our admirals are being furnished with a full line of their specialty for use in operating against Spanish fleets.

THE BALLARD ELECTRIC COMPANY, of Chicago, has certified to a change of name to the Wells, Goodhue Company.

WESTERN ELECTRIC COMPANY has incorporated in the State of Michigan, with a capital of \$1,000,000, with headquarters at Detroit.

COLUMBIA LAMPS. Mr. A. C. Garrison, secretary of the Columbia Incandescent Lamp Company, of St. Louis, states that they have experienced a steadily increasing demand for their lamps during the past year, and will now be obliged to enlarge and alter their factory during August. They therefore ask that any orders may be sent to them as early as possible. It will be a convenience and will ensure prompt shipment during the next sixty days.

NEW YORK NOTES

AMERICAN IMPULSE WHEEL COMPANY, of 120 Liberty street, New York, have secured the contract for furnishing water wheels for the lighting station for the city of Columbus, O.

PITT & SCOTT, the well-known foreign freight brokers and express carriers, of 39 Broadway, have just issued the eleventh edition of their admirable little book of "Useful Notes," intended for travelers in Europe. It is full of information and serves as a vest pocket Murray or Baedeker.

BURGER & ADAMS. Mr. Clarence Livingston Burger, the

patent attorney and expert, has associated with him in the practice of patent and trade-mark law Mr. Louis B. Adams, under the above firm name. The offices of the firm remain in the Postal Telegraph Building, 253 Broadway, where Mr. Adams continues also the practice of the law.

MR. S. GLOVER WAY, of late with the General Incandescent Arc Light Company, has just entered the employ of Messrs. Osterberg & Sutton, consulting engineers, as their superintendent of construction.

McINTOSH, SEYMOUR & Co. have booked orders for two 700 h. p. horizontal cross compound engines to be used in the City of Mexico. They will be directly connected with two 452 k. w. General Electric generators, for trolley work. A 150 h. p. engine has also just been sold by this concern to the Kimberley mines of South Africa. This engine will be directly connected to two 50 k. w. generators of the double-end plan.

The Electrical Engineer.

Vol. XXVI.

JULY 28, 1898.

No. 534.

New Work at Niagara Falls by the Hydraulic Company.

BY ORRIN E. DUNLAP.

THE Niagara Falls Hydraulic Power & Manufacturing Company have just placed in operation the first turbine and generator located in the extension of their power house in the gorge. This extension of the company's plant has been in progress for some months. The addition made to the building is 60 feet long by 100 feet wide, and the total dimensions of

PENSTOCK OF NEW INSTALLATION OF N. F. H., P. & MFG. CO.

the power house to-day are 120 by 100 feet. The addition is of the same style of architecture as the original section of the building, and has been built on the south end. The partition between the two sections has been removed, throwing the entire floor into one. Many readers of *The Electrical Engineer* have visited the Falls and personally inspected the installation in the first section of the power house, and will remember that it consists of four turbines made by James Lefel & Company, of Springfield, O., which operate eight generators. The new turbine and generator just installed stand out further toward the west wall of the building than any of the machines first installed. A gallery-like structure has been built close to the cliff wall and on it the switchboards of the old and new installations are located. This is quite a noticeable improvement, and was made under the supervision of Frank G. Lott, the company's chief electrician and superintendent.

The property of the power company presents a scene of activity at all points. On the canal men are busy with the

work of enlargement, and over the new forebay a steel gate house has been erected. Out from beneath this extend the walls of the new connecting canal running from the main canal basin to the forebay. The walls of this canal are built of concrete, and are most substantial in appearance. It will be remembered that in building the forebay extension a large amount of concrete was used, the company finding it most serviceable for this class of construction. As the connecting canal passes under the New York Central Railroad tracks it is made water tight beneath the roadbed in order that high water will do no damage.

The penstock that will supply the new wheels with water is larger than the one that supplies the wheels in the original section. It is about 11 feet in diameter and leaves the forebay in an elliptical bell mouth about 20 by 11 feet. For 60 feet it extends out horizontally, and then vertically about 200 feet to the power house. It stands out from the cliff in column form, and attracts immediate attention. As it passes beneath the power house floor the diameter increases to about 13 feet for a distance of 50 feet, and then reduces until it is about 7 feet, finally tapering in a cone 18 inches in diameter and ending in an air chamber 15 feet high and 4 feet in diameter. Along its course under the floor there are five 60-inch valves for supplying the wheels. The thickness of the steel in the penstock varies from $\frac{3}{4}$ to $1\frac{1}{8}$ inches. It was made by Struthers, Wells & Co., of Warren, Pa.

The number of wheels to be installed is five, the first of which has been built and installed by R. D. Wood & Co., of Philadelphia. Its capacity is 2,500 horse power, and it has been

ALUMINUM CABLES RUNNING ALONG PENSTOCK OF NEW INSTALLATION OF N. F. H., P. & MFG. CO.

placed over the last of the five valves on the penstock. The general appearance of the wheel is very similar to that of the wheels installed in the original section of the station, but its construction varies somewhat. Generally speaking, the wheel may be said to be the same as those used by the Niagara Falls Paper Company, there being but a slight difference between them, which is to be found in the curve of the buckets, a difference made necessary by the fact that the head of water at the paper mill is about 140 feet, while in the station under discussion the head will be about 210 feet. This wheel is known

as the Jonval-Geyelin improved. It consists of a large, vertical circular casing in which the wheels proper are located, for there are two wheels within the case. The water is admitted underneath and flows upward, being admitted to the guide wheels by a gate and then to the runners. The discharge pipes project from the sides of the casing laterally and downwardly, draft tubes 22 feet 8 inches long being attached, thus utilizing, in part, the atmospheric pressure. The heads of the large casings are more oval and not quite so high as the casings about the wheels in the original section of the building. The heads are made of cast iron $1\frac{3}{4}$ inches thick and have heavy $2\frac{1}{2}$ by 6 inch ribs at the bottom. The casing weighs about 10 tons, while the total weight of the wheel installed is about 21 tons. It rests upon a pair of 24-inch steel I beams. The wheels are made of bronze and are located in draft tubes, one on each side of the casing proper, upon a horizontal shaft. This shaft is supported by a rigid bearing with the flush bearings bolted to rigid bearings. The disc that forms part of the flush bearings is keyed to the shaft and adjusted by four heavy set screws, one on each side of the shaft, to take up the thrust. The wheels discharge laterally into the discharge or receiving pipes. Four $2\frac{3}{4}$ rods extend through the casing to stiffen it. The two wheels weigh 5,095 pounds. In designing this turbine, special care was taken owing to the great pressure on the component parts, and especially on the gates, which are planned on a slide motion principle and are counterbalanced, a simple but effective method of overcoming the enormous pressure which would act on each individual turbine gate.

The gate used is a ring gate, which revolves on a barrel. This

NEW TURBINE AND GENERATOR IN STATION OF N. F. H., P. & MFG. CO.

is fastened to the guide wheels by bolts, and the gate is operated by a walking beam, which works over the top of the case proper. The gate is connected to the beam by steel gate rods $2\frac{1}{2}$ inches in diameter, which extend down through glands into the casing. Cast steel brackets are riveted to the gate and to these the gate rods are connected. The runner has 34 buckets with a total area of 140.25 square inches. The guide wheel has 20 buckets having a total area of 149.53 square inches. Over the walking beam there rises an air cylinder which is about 36 inches high, and has an inside diameter of $20\frac{1}{2}$ inches. It is understood the Reynolds governor will be used on the wheel. Provision has been made for disconnecting the governor by simply operating a wheel which unscrews a rack. E. H. Broome, one of R. D. Wood & Co.'s most efficient engineers, was in charge of the work of installing the wheel, Mr. Broome being the Niagara Falls representative of the company.

It is intended that this wheel shall operate two generators. One of these machines already furnishes current for the operation of the National Electrolytic Company, while the other will add to the supply of the Buffalo and Niagara Falls Electric Light and Power Company. The generator for the service of the first named company has been installed by the General Electric Company. This machine has 14 poles and will make 250 revolutions per minute. Its output will be 5,000 amperes at 175 volts, or a capacity of 875 kilowatts, nearly 1,200 horse power. It is of a large type and direct connected to the water wheel shaft on the left. The factory that will use the

current from this machine is located on the high bank above. Aluminum will be used as the conductor between the generator and the plant. The lower portion is erected in the form of bars, and the upper portion in the form of insulated cables. This style of conductor is the first of its kind put in use. The aluminum cables of the original installation have given entire satisfaction, a fact which has led to the still further adoption of the white, light metal.

The Buffalo and Niagara Falls Electric Light and Power Company take a portion of their current supply from the Niagara Falls Power Company and a portion from the Niagara Falls Hydraulic Power and Manufacturing Company. Their main station is located near 14th street, opposite the central station of the Niagara Falls Power Company, but they have a very efficient installation in the basement of the Cliff Paper Company's mill, and it is this installation that the new generator and connection will do away with. The generator is now being made by the Walker Company, of Cleveland, O. It will be an alternating current dynamo of 700 kilowatts capacity at 2,200 volts pressure, to be operated at 250 revolutions per minute and at 125 cycles per second. A continuous current exciter of sufficient capacity to supply current to the fields of the above mentioned dynamo to permit of its producing 1,100 kilowatts at its standard voltage, should such be required for a short time, will also be installed. The switchboard for this machine will be of blue Vermont marble and will be mounted with all the necessary instruments and appliances.

It is a very noticeable fact that both of the large power companies at Niagara stand ready to adopt everything they feel will make an improvement in their installations. For this reason the new installation of the Niagara Falls Hydraulic Power and Manufacturing Company shows several changes over the original plant. Chief among these is the series of iron posts and beams placed in the tail race beneath the power house floor to support the penstock and wheels. All parts of this work have been made adjustable by a series of keys, the work having been done by the Variety Iron Works of Cleveland, O. The new tail race is a little larger than the old one, and is most substantially built.

All the work of the Niagara Falls Hydraulic Power & Manufacturing Company is done under the supervision of Wallace C. Johnson, M. Am. Soc. C. E., who is president of the Engineers' Society of Western New York. Mr. Johnson is especially pleased with the new installation, and feels that future visitors to the plant will admire its many merits. In this connection it may be stated that Mr. Johnson has become known as an engineer of high authority on power development, and has been consulted in regard to many very promising projects in which capital has invested or is about to invest.

A few words must be added with special details of the aluminum conductors. From the power house to the top of the bank these conductors are in bar form. The bars are 25 feet long, $\frac{1}{2}$ by 6 inches in thickness and width, and four are placed in parallel. The bars are riveted and bolted every 25 feet, and they extend from the power house to the top of the bank along the side of the big new penstock, the erection being on brackets. At the top of the bank they are connected to the aluminum cables, twelve of which are on each leg. In diameter the aluminum part of the cables is about $1\frac{1}{4}$ inches, covered with rubber insulation. The size of the wire in the cables is about No. 10. The bars are connected to the cables by castings, which contain sockets, just holding the ends of the cables. These ends are placed in the sockets and melted tin is poured about them, making a solid permanent joint. The total amount of aluminum used in the installation is about 22,000 pounds. The same work in copper would call for about 48,000 pounds. The conductivity of aluminum as compared with copper in same section is 63 to 64 per cent., and more than double for the same weight. One important feature demonstrated in the erection of the new aluminum conductors at Niagara was the ease with which they were placed in position, as compared with the work of erecting copper cables. The high cliffs along the Niagara gorge, at the point of the installation do not offer many advantages for easy placing of materials, but the aluminum conductors, owing to their lightness of weight, were easily handled, and erected with rapidity. While it is a fact that aluminum cables require more insulation than copper, it seems very likely that there is a field for the use of aluminum in feeder cables. There is little doubt but that the extra cost of

the insulation would be met by the manufacturers in the price of the metal, especially on large orders. The lightness of the aluminum cable, also its strength, would make it possible to use the aluminum conductor in much longer spans, thus doing away with the cost of the extra poles and insulators now required by copper, which in miles of line is no small factor.

The aluminum conductors referred to are the second set installed by the Niagara Falls Hydraulic Power & Manufacturing Company, thus attesting their confidence in the metal. The first set of aluminum conductors placed by them runs from the original installation in their station to the lower works of the Pittsburg Reduction Company. These conductors are in the form of huge cables, two in number, with 250 strands in each, insulated. The new conductors are neater in appearance and extend to the top of the bank outside of the penstock, while the large cables referred to run up the cliff through a tower.

The Welland Power Canal.

THE Welland Power & Canal Supply Company still have hopes that they will be able to carry their project through. This company holds a franchise for the construction of a power canal from the Welland River to the brow of the mountain at Thorold, Ont., a distance of about eight miles. From the mountain they would carry the water to Lake Ontario by means of a raceway, possibly using the water at another level. Henry Symons has just returned from England, where he went to see what could be done with the project and to secure estimates on its probable cost. It cannot be said, however, that the figures are altogether encouraging. Mr. Symons, realizing that a market for the power might be an incentive to capital to invest, secured estimates also on the construction of a transmission line from Thorold to Toronto by way of Burlington Beach. The estimates Mr. Symons has given out were prepared by Dr. John Hopkinson, F. R. S.; Edmund Wragge, formerly of Toronto; Sir Douglas Fox and Prof. W. Cawthorne Unwin. Prof. Unwin's name in connection with the estimates excites interest in this country because he is known to have had prominent connection with the great development at Niagara Falls, having been a member of the International Niagara Commission organized by the Niagara Falls Power Company to solve the problem of the then prospective Niagara development. In the estimates given it is stated that the machinery to generate 100,000 horse power will cost £125,000; the excavation and other work connected with the project, £1,525,062; the transmission line to Toronto, at a voltage of 10,000 and delivery of 50,000 horse power, £801,600, making a total of £2,542,162, which is in the neighborhood of \$12,000,000. If the amount to be delivered in Toronto is reduced to 20,000 horse power, it would cost \$1,000,000 less. Naturally, long term contracts with Hamilton and Toronto for power would aid the company's ideas.

The Abuse of the Power Station.

Mr. W. H. Preece read a paper before the Incorporated Association of Municipal and County Engineers at Yarmouth, in which he calls attention to the abuse of the power station. He says the great tendency to multiply power houses arises from (1) want of foresight in predicting the growth of electric industries; (2) economy in selecting land we have, rather than pay money for land more suitable by position, out which we have not; (3) the restriction of legislation in confining operations to a defined area; (4) the growth of other industries side by side, especially tramways and railways worked by electric traction. He also points out that if a plant—say 10,000 k. w.—working at its minimum load on the average three hours a day produces electrical energy at one penny (2 cents) a unit, it will do so at three farthings (1½ cents) per unit if it works six hours a day, one halfpenny (1 cent) per unit if it works twelve hours a day, and less than a farthing (½ cent) per unit if it works twenty-four hours a day. One large station conveniently built on the water-side where coal can be delivered alongside, by rail or sea, at its cheapest; where water is abundant and available for condensing, where ashes, clinkers and dirt are easily barged away, is clearly the ideal power house for economy.

MASS. CHAR. MECH. ASSOCIATION announces that the General Electric Company will make a working exhibit at the twentieth triennial exhibition to be held in Boston in October.

Combined Trolley and Accumulator Traction System in Paris.

AN interesting application of electric traction has just been carried out in Paris by the French Thomson-Houston Co. on the tramway lines of the Place de la République d'Auber-villiers and to Pantin. Within the limits of the city of Paris the roads are operated by accumulators, and beyond the limits by means of overhead trolley. The two lines about to be described have in Paris a total length respectively of 3¼ miles and 4.2 miles, with a common track of 1½ miles. Beyond the

FIG. 1.—COMBINATION BATTERY AND TROLLEY CAR, PARIS.

city limits the two lines are 1 mile and 1½ miles in length, respectively. There are also three other lines which run into other villages at the gates of Paris.

The roadbed has been installed by the Paris Tramway Co. and by the Department of the Seine. The rails are of the Broca section, about 90 lbs. to the yard for the middle of the road, with rails of the Vignole section when they run side by side. The cars employed, shown in Fig. 1, have double decks and carry 56 passengers; that is to say, 4 on the platform, 24 inside below, and 28 on the upper deck. They may be criticized as being too large; it would be preferable to assure good service to have the cars smaller and have them run oftener. Aside from this, however, the cars are very well designed.

FIG. 2.—STORAGE BATTERY USED ON COMBINATION TROLLEY AND BATTERY CARS, PARIS.

They rest on bogie trucks, which permit of utilizing the traction of both motor trucks.

The cars are the same at each end, so that they can be run in either direction without turning at the terminal points. Each truck is operated by an electric motor of 25 h. p. and controllers are placed on each platform. Each car is provided with sand boxes, with ordinary brakes and with electro-magnetic

brakes on each truck. The latter are able to stop within less than 43 feet, with a car loaded with 4.4 tons on a down grade of 2.4 per cent. running at a speed of 12 miles an hour. The cells, Fig. 2, furnished by the Société pour le Travail Electrique des Metaux are 224 in number, of 7 plates each, with a capacity of 35 ampere hours. The plates have a height of 12¼ inches and are 0.36 inches thick, enclosed in ebonite boxes. The box which holds the batteries, and which is placed under the car, as shown in Fig. 3, is 6 ft. 6 in. long, and 8 feet wide and ¼ ft. high. The electric equipment of each car is such that the motors can be operated either from the battery or from the trolley current, which also at the same time charges the storage batteries. Each car is lighted by 10 incandescent lamps of 16 c. p. each.

The power house is situated at d'Aubervilliers, and is divided into two principal parts. On one side is the boiler room, the engine room and the repair shop for the accumulators. On the other side are the tracks for the storage of cars, with arrangements for complete inspection.

The boiler house contains three multitubular Roser boilers.

FIG. 3.—BATTERY IN PLACE ON COMBINATION TROLLEY AND BATTERY CARS, PARIS.

In the engine room are three single cylinder, horizontal Corliss engines built by Garnier, of 250 h. p. each, running at 75 revolutions per minute. Each engine drives a Thomson-Houston compound 6-pole dynamo of 150 k. w., generating 550 volts at 400 revolutions per minute. These machines are built by the firm of Postel-Vinay. The same machines can be driven as shunt dynamos of 575 volts for charging accumulators. Two main circuits are taken from the switchboard, one at 530 volts for feeding the trolley lines, the other at 575 volts for charging accumulators while en route. The four feeders can be branched as desired either on one circuit or the other.

Such are the main arrangements as described by Mr. J. Laffargue in "La Nature" of the new mixed accumulator and trolley system which seems to answer perfectly to the present requirements of traction in Paris.

Buffalo-Niagara Trolleys.

The Buffalo, Tonawanda & Niagara Falls Electric Railroad Company, on Saturday, July 16, opened for traffic a new extension of their lines. This new line begins at the corner of Tonawanda and O'Neil streets, on the northerly limits of the city of Buffalo, and follows O'Neil street to Niagara street, thence along Niagara street about one mile to a ferry on Niagara River, which runs between the terminal of this new extension and various resorts on Grand Island. This line will be further extended along Niagara street to the village of Tonawanda, and will prove to be a popular electric line between Buffalo and Niagara Falls, as it follows the high banks of the Niagara River the entire distance in full view of the beautiful scenery of that river and Grand Island. Henry B. Smith, of Bay City, Mich., is principal stockholder.

A Decision for Electric Cabs in Paris.

The Compagnie Generale des Petites Voitures in Paris has now definitely given the preference to electrical cabs over those using petroleum as a motive power. The latter are held to have a disagreeable odor and are less manageable than the electric.

DETROIT, MICH., has been agitating and petitioning for the handling of light freight on the city street railways.

Notes From the Field—Electricity on the Pittsburgh Street Railways.—II.

BY C. B. FAIRCHILD.

UNITED TRACTION COMPANY.

THE mileage of this system is located on both sides of the Allegheny River, covering portions of Pittsburgh and of Allegheny. The power is concentrated in two stations, one in Pittsburgh, on Second avenue, the other in Manchester. The latter station has recently been enlarged and re-equipped with new engines, generators and boilers. The addition to the building consists of a brick extension running the whole length of the building, parallel to the engine room, and which constitutes the new boiler room. In the original equipment the boilers were located at the end, instead of at the side of the boiler room. By the new arrangement, the relative distance between boilers and engines has been maintained, and both can be extended uniformly when necessary. The ground dimensions of the building are 135x157 feet, the engine room being 75 ft. in width. The new equipment, which entirely replaces the old, consists of four direct coupled tandem compound condensing Green engines, having cylinders of 20-38x48 inches, and nominally rated at 800 h. p., but can be run up to a maximum of 1,200 h. p. each. The generators, which are of Westinghouse manufacture, are each of 500 k. w. capacity, with special wiring to secure ventilation, and are guaranteed to stand 25 per cent. overload for eighteen hours, without increasing the temperature above 40 degrees. The shells of the main bearings on the engine bed are all cast hollow for water jacketing, should it become necessary to employ water for cooling the boxes. Another feature consists in so leading the oil to the cylinder that it falls directly on to the valves, securing better lubrication than when introduced into the steam pipe. The steam pipes are arched and lead directly from the steam drums over and down to the cylinder, avoiding angles and joints. The steam generating equipment consists of eight 400 h. p. water tube boilers, of the Sterling type, which are fired by Murphy stokers, the coal being fed by gravity from self-measuring and recording hoppers, located above the furnaces. The cars for delivering coal run into the boiler room on an elevated track and discharge their coal into a storage vault beneath the floor, which runs the whole length of the boiler room, the retaining walls being of stone. From the vault it is elevated to the hoppers by means of a traveling elevator operated by an electric motor, which is mounted upon a platform on the elevator itself. This elevator or conveyor runs upon a track which is located near the bottom of the pit, and also upon a track at the top. The motor furnishes power both for driving the bucket and for moving the elevator along the track, the latter movement being effected by throwing a clutch that connects the wheels at the base with the motor. In operation the elevator is brought opposite one of the delivery spouts in the bin, from which when the gate is open the coal runs directly into the buckets of the elevator, and is raised to the hoppers and delivered by gravity, as required, to the stokers through the self-registering and self-weighing chutes.

The elevator was erected by Heyl & Patterson, of Pittsburgh. The same conveyor removes the ashes from beneath the fire boxes, and elevates and discharges them into cars or carts for removal. The auxiliary steam equipment includes condensers built by Dunn & Dorton, of Cincinnati. The condensing water is drawn through a 20-inch main, from a cement lined cistern, located along the outside wall of the engine room. This cistern is 100 ft. in length, and has a cross section of 10x8 feet, and is filled by pumps located in a well 17 ft. below the coping. This well is 60 ft. deep, and 12 ft. 6 in. in diameter, and communicates with a brick tunnel 4 ft. 6 in. in diameter, and 60 ft. in length, which extends under the bed of the river to the edge of the channel, and which terminates in a filtering crib. The condensers are protected from high water by cement walls, although it is high enough sometimes to flow directly into the cistern. Filtered water from the condensers is used for feed water, although water from the city mains can be employed. The switchboard is of Italian marble, and is 45½ ft. in length, with panels for six generators and 20 feeders. The board is designed for a three wire system, although the road at present is not operated with three wires. The three bus-bars are made up of copper plates ⅛-inch in thickness, and 3 inches wide, and each one contains sufficient copper to run the whole road, if necessary. The board is equipped with West-

inghouse instruments with the lighting switch independent of the circuit, so that it does not leave the station in darkness when the circuit breakers are opened. A special six-pole switch is provided for the lighting circuit, which connects with each machine. This is placed at the middle and near the base of the board. Two cables from each terminal of 650,000 c. m. capacity each lead down under the floor to the switchboard, from which the feeders go out over poles for distribution.

One of the features connected with the operating department worthy of note is a wheel grinding machine, which was designed by the general manager, and which will grind the wheels without removing them from the car. The car being jacked up, the wheels revolve by their own motor, while emery wheels driven by stationary motors are revolved against them or in contact with them in the opposite direction. With this equipment the cost of grinding wheels is estimated to be from 50c. to 60c., as against a cost of from \$3 to \$7 where wheels have to be removed for grinding. Electric transfer tables are employed in the repair shops, which are equipped with discarded car motors, and which take the current from an underground trolley. The standard type of motors employed on the cars of this company are the Westinghouse No. 38, and the trucks are nearly all of the Lord Baltimore type. Three cars on the system are equipped with the Clark hydraulic brake. There are also five equipments of Walker No. 50 motors. One double truck car having four motors, has recently been equipped with the new Walker type S. controller. This controller is provided with solenoid blow-outs, and is working very satisfactorily. The president of the United Traction Co. is James D. Callery, and the General Superintendent is John Murphy.

Some Phases of the Rapid Transit Problem.¹

BY ALBERT H. ARMSTRONG.

AS running at a constant speed does not occur in rapid transit service where stops are at all frequent, it becomes of the greatest importance to carefully investigate the subject of train acceleration in order to determine the method of running a train from station to station with the least expenditure of energy.

Problems in train acceleration may be divided into two broad

with frequent stops, over 80 per cent. of the total energy output of the motive power on level roads is required to accelerate the train, it is evident that in this class of service the rolling stock requires the greatest attention.

To avoid undue complication, the following discussion has assumed that train friction is a constant quantity at all speeds, as at the low maximum speeds—20 to 30 miles per hour—reached in practice with frequent stops of two or more per mile, the error introduced by assuming a constant friction rate will be small and will not at all alter the conclusions arrived at.

The following constants have been assumed as representing average operating conditions: Length of run, 2,000 feet. Length of time train is in motion, 75 seconds. Schedule speed, 16.05 miles per hour, including 10-second stops, or 85 seconds total time. Tractive effort, 100 pounds per ton total, to be maintained uniform during acceleration of the train. Braking effort, 150 pounds per ton constant throughout the period of braking. The train friction being 15 pounds per ton, reduces the effective accelerating force from 100 to 85 pounds per ton, corresponding to a rate of .927 miles per hour per second.

With this data a simple acceleration curve may be calculated, the train reaching a maximum speed of 28 miles per hour in 30 seconds, when power is shut off and the train allowed to coast with a retardation due to friction of .1635 miles per hour per second for 31 seconds to the braking line, when it is retarded at a uniform rate of 1.635 miles per hour per second and comes to rest in 75 seconds from time of starting.

It is obvious that the train could be accelerated at a different rate than that corresponding to 70 pounds per ton and still make the same length of run in the same time, the length of time occupied in coasting depending upon the rate of acceleration, being a maximum with an infinite rate, that is, with the train starting with a certain initial velocity. A minimum rate of acceleration is reached when no time is left for coasting, that is, when brakes are applied as soon as power is shut off. In Fig. 1 such a set of curves has been prepared showing a train covering a distance of 2,000 feet in 75 seconds, as before, but accelerating at various rates from that corresponding to 62.8 pounds per ton as a minimum up to an infinite rate, or starting with an initial velocity of 25.2 miles per hour.

As the area enclosed by time as abscissæ and speed as

FIG. 1.—SPEED AND ENERGY CURVES. (Distance, 2,000 feet. Time, 75 seconds. Friction, 15 lbs. per ton. Braking Effort, 150 lbs. per ton.)

FIG. 2.—SPEED AND ENERGY CURVES. (Distance, 2,000 feet. Friction, 15 lbs. per ton.)

FIG. 3.—ENERGY CURVES ON ARTIFICIAL PROFILE. (Distance, 2,000 feet. Time, 75 Seconds. Starting Grade of 4 per cent. Tractive Effort of Motors, 100 lbs. per ton. Friction, 15 lbs. per ton. Braking Effort, 150 lbs. per ton.)

classes: 1. Where the road is level; and 2. Where grades exist or where an artificial profile is made in order to take advantage of down grades at starting.

Modern passenger cars demand a dead weight of approximately 550 pounds for each passenger carried, or, in other words, only 20 per cent. of the total weight of a loaded motor car is a paying load. When it is considered that in rapid transit service

ordinates represents the distance covered, this will be a constant quantity for the fixed distance of 2,000 feet assumed, and curves of Fig. 2 are thus constructed with the same enclosed area for each rate of acceleration. The fact is plainly brought out that with a low rate of acceleration a much higher maximum speed is demanded than would be the case if the rate had been increased, and a curve may be plotted by joining the maximum speeds reached for different accelerating rates, as shown.

It is advisable in rapid transit service to keep the maximum

¹Abstract of a paper read at the 15th General Meeting of the A. I. E. E., Omaha, June, 1896.

speed reached by the trains as low as possible, as this class of work generally calls for a short time interval between trains where the utmost precautions are necessary to keep the trains a safe distance apart. In fact, the maximum speed required for a given run practically determines the time interval between trains, as the train headway should be at least five or six times the length of time required to bring a train to rest from its maximum speed with normal braking force applied.

A second reason for higher rates of acceleration lies in the fact that with rates of acceleration approaching the minimum no margin is left for errors of judgment of the motorman, as little or no time is left for coasting, and the rate of acceleration per ampere input is continually varying with the changing passenger load and hence with an overload it becomes difficult to maintain schedule speed. A third and most important objection to the use of a low rate of acceleration lies in the saving of energy for the run by the use of a higher rate.

Neglecting $I^2 R$ and core losses of the motors, a set of energy input curves per ton weight of train may be plotted as in Fig. 1, assuming for simplicity that motors are series wound, operate all in multiple and are so geared that starting resistance is entirely cut out at the various maximum speeds reached in the various runs, that is, that no accelerating is done on the motor curve. A constant impressed e. m. f. is assumed, and starting resistance is supposed to be cut out proportional to the motor speed, thereby keeping the current and torque constant.

Thus it is seen that accelerating a train with the minimum rate calls for the highest maximum speed, demands nearly the least current input and also demands the greatest waste of energy in the brakes, as the speed is a maximum when brakes are applied.

The areas enclosed by the various energy time curves represent the comparative amounts of energy required for the run for the different rates of acceleration and these are plotted in Fig. 1, which compares the energy input and the average energy consumption for the run of 2,000 feet in 75 seconds for all rates of acceleration from the minimum corresponding to 62.8 pounds per ton up to infinity.

For convenience the average energy rates are plotted in terms of watt hours, and the curve shows that while the minimum rate of acceleration corresponding to 62.8 pounds per ton calls for an expenditure of 83.5 watt hours per ton weight of train, this is reduced to 56.5 watt hours by accelerating with a rate corresponding to 70 pounds per ton, to 42.7 watt hours with 100 pounds, and finally reaches a minimum value of 32.5 watt hours if the accelerating rate is pushed to infinity.

Thus the energy required for the run of 2,000 feet in 75 seconds may vary from 83.5 to 32.5 watt hours per ton of train weight, a decrease of over 60 per cent., depending upon the rate of acceleration used.

The error made in accelerating at or near the minimum rate is clearly brought out. For example, the current consumption per ton is the same for 62.8 pounds per ton or 85 pounds per ton; as, although 85 pounds calls for the greater tractive effort, the torque per ampere is so increased by the lesser maximum speed demanded that the current input is the same in each case, hence the feeder considerations are the same in both cases, while the energy consumption shows a reduction from 83.5 watt hours per ton with 62.8 pounds to 47.5 watt hours, or about half, with 85 pounds per ton.

Referring again to Fig. 1, it is obvious that a similar set of curves may be plotted for a run of 2,000 feet for any other length of time than 75 seconds, and the author gives such a set of curves plotted for lengths of time ranging from 41 seconds, as a minimum possible, up to 210 seconds.

To compare the amounts of energy required for rates of acceleration other than the maximum and minimum, a set of curves has been prepared in Fig. 2 giving the energy consumption for a run of 2,000 feet on a level track for any rate of acceleration and for any length of running time, the constants being 15 pounds per ton friction rate and 150 pounds per ton braking effort. For convenience in comparison, the energy consumption is reduced to watt hours per ton mile, and speed is expressed as average speed in miles per hour while train is in motion or equaling schedule speed if the train loses no time in stopping. The dotted curve a b is the maximum energy curve and the curve c d represents the minimum amount of energy possible for the different speeds and is described by an infinite rate of acceleration.

The curves of maximum and minimum energy consumption approach each other and coincide at a speed of 33.3 miles per hour, corresponding to an energy consumption of 298 watt hours per ton mile, this value being the greatest amount of energy that can be expended on the run with 150 pounds per ton braking effort.

All energy values are net, that is, they represent the amount of energy required to accelerate the train plus energy lost in overcoming friction, and hence take no account of any losses occurring in actual operation in the motors, rheostats, gearing, etc.

Fig. 2 shows the economy resulting from properly proportioning the accelerating rate to the schedule speed and distance traveled. For example, a train accelerating with a tractive effort of 100 pounds per ton and making 20 miles per hour average speed, not including stops, will require 127 watt hours per ton mile, which would be reduced to 65 watt hours per ton mile if the tractive effort had been increased to 150 pounds per ton, or, in other words, the generator capacity would be but half as large for the same service.

The curve of 300 pounds per ton tractive effort is interesting as it represents about the maximum speed attainable with modern apparatus for a distance of 2,000 feet with the assumed constants of friction and braking effort. Assuming the entire weight of the car to rest upon drivers, about 300 pounds per ton would be available for traction without slipping the wheels on an average track, so that an average speed of 26½ miles per hour is the highest that could be obtained over a distance of 2,000 feet, not allowing any time whatever for coasting.

All previous curves have been based upon the assumption that trains are allowed to coast after reaching maximum speed, and also that acceleration is carried on at a perfectly uniform rate until power is shut off, but in practice this assumption may be modified somewhat, the starting resistance being cut out before the maximum speed is reached, and the latter part of the acceleration carried on at a constantly decreasing rate upon the motor curve.

Another method would be to accelerate at a constant rate until maximum speed is reached, then continue this speed constant by supplying motors with just sufficient power to overcome train friction. This latter method of train acceleration, however, demands such a considerable increase in the amount of energy required for the run that it has not hitherto been considered.

The area enclosed by the energy time curves is a measure of the average energy consumption for each run, and their respective values reduced to watt hours are: a. Constant current and coasting, 147 watt hours per ton. b. Constant current and no coasting, 160 watt hours per ton. c. Constant current and acceleration on motor curve, 126 watt hours per ton.

Of the three methods, the one making use of the acceleration due to a series motor curve, not only requires the least maximum current input, but also requires the least average energy input to the motors for a given run and hence is the form of curve used in the majority of actual runs.

Whatever form of acceleration curve be used, the results arrived at in Fig. 2 will not be greatly modified if similar forms of curves are compared, and, being expressed in terms of actual work done, may be used for any run with a factor expressing the efficiency of acceleration: that is, the ratio of actual work done to the total energy input.

It will be noted that all curves of Fig. 2 approach a minimum value of 30 watt hours per ton mile, that is, the minimum energy expressed in watt hours per ton mile expended for a given run will be double the friction rate. The actual factor is 1.98 and forms a very convenient method of determining the net energy consumption for any speed and train weight if the friction rate be known. Thus, assuming the light load efficiency of a railway motor, including gear loss, to be 75 per cent., a friction rate of 15 pounds per ton would demand an input of 40 watt hours per ton mile, corresponding to an input of 1,200 watts per ton weight of train at, say, a constant speed of 30 miles per hour.

A number of interesting conclusions may be made from the foregoing investigation of the operation of trains upon a level track.

1st. The rate of acceleration determines the energy consumption for a given run, and since this energy consumption decreases with increased rate of acceleration, the train should be brought up to speed as quickly as possible and allowed to coast to secure the minimum energy input.

2d. The maximum current input during acceleration increases with the rate of acceleration, and hence limits the rate at which a train can be accelerated with a given feeder loss or feeder investment.

3d. In order to reduce the average energy consumption and also the maximum current input to a minimum for a given run, a due amount of acceleration should take place on the motor curve after starting resistance is cut out, hence a motor should be carefully proportioned for the work it has to do.

4th. A normal amount of coasting should be permitted after power is shut off, partly to provide a margin to allow for errors of judgment of the motorman, but largely because this is the most efficient method of accelerating a train. On no account should the maximum speed be continued by supplying the motors with just sufficient current to overcome train friction, as this method of accelerating is extremely wasteful and inefficient.

Having discussed various methods of accelerating, it is interesting to follow out the problem, and determine the actual efficiency of transporting passengers by our modern methods of travel. It has been pointed out that only from 15 to 20 per cent. of a fully loaded train consists of a paying load, and with an average load as carried throughout the day this percentage will be reduced to 10 per cent. or less, that is, nine-tenths of the energy consumed in moving this train at a constant speed is wasted. But in rapid transit work a train seldom attains a constant speed, due to the frequent stops and high schedule speed, and at least ten times the energy required to overcome friction alone must be expended in accelerating the train, only to appear as heat in the brake shoes when bringing the trains to rest. That is, considering the friction work of the train as the only useful work done, an efficiency of only 10 per cent. is reached in the average run. But only 10 per cent. of this friction work is useful in moving passengers, hence the actual passenger efficiency is reduced to less than one per cent. of the total energy delivered to the train during acceleration.

When it is considered that further losses occur in operation in the motors and their method of control, in the transmission lines and generators of an electric traction system, it will be appreciated that the present method of transportation, with its efficiency of a fraction of one per cent., opens a wide field for improvement. This applies with greater force to rapid transit service using steam locomotives as a motive power, as the dead weight carried per passenger is greater with a steam locomotive than with a motor car, and the efficiency from the coal pile is much less. Hence some means of reducing the large loss, due to accelerating the train is desirable, and this is found in the adoption of an artificial profile, as followed out in a large underground road now building, using down grades in starting, and up grades to retard the train when stopping.

The ideal profile would provide for a down grade at starting sufficient to do the work of acceleration and with an up grade to do the entire braking required, thus leaving only the friction energy to be supplied by the motive power. Such a road would operate at 100 per cent. efficiency, neglecting the dead weight of train carried and considering total friction work as useful work.

Reduced to practice, this ideal grade must be modified considerably. The per cent. grade used is limited partly by the rapidity of acceleration that may be imparted to the train without discomfort to the passengers and partly by the available tractive effort of the motive power, which must be sufficient to haul the train up the grade in case of necessity.

A second modification occurs in the necessity of having stations placed on a level track, and since a train has an appreciable length, it must travel its own length before the last car is off the level and the full effect of the grade is felt. Thus, during the first period of acceleration the rate is comparatively small and must be furnished by the motors, resulting in a material reduction in the energy gain in the theoretically ideal profile. An artificial profile can only be secured on elevated or underground roads, and a double track road necessitates two separate overhead structures and the underground road must consist of two separate tunnels with unlike profiles.

Assuming two stations to be on the same level, there are two forms of profile that may be assumed with a given maximum difference in levels, as shown in Fig. 3. Profile a consists of a down grade with a level track at each terminus equal to the length of train operating over the road, while profile b consists of a down-grade and up-grade equal in length and percentage

with a level track connecting them, and also a level track at each station equal to a train length.

In practice a perfectly symmetrical profile, as in b, will not be possible, as the level tract connecting grades must be replaced by a slight grade to provide for drainage in tunnel roads, this grade preferably opposing the direction of movement of the train.

In order to ascertain the behavior of a train upon the two forms of profiles and to determine the most efficient form of grade, a series of curves have been plotted upon the following assumptions.

Length of run total, 2,000 feet; train friction, 15 pounds per ton constant; braking effort, 150 pounds per ton during time brakes are set; running time, 75 seconds; length of train, 200 feet, corresponding to an average train of four to five cars; tractive effort, as supplied by motors, 100 pounds per ton. (This effort being supplied irrespective of added effort due to grades.) No running is assumed to take place on the motor curve, and train is supposed to coast after reaching maximum speed. Motors are controlled by the ordinary series parallel method, starting with two motors in series and throwing them into multiple, the starting resistance being supposed to be cut out uniformly so that 100 pounds per ton motor effort is maintained constant while current is on.

Due regard is paid to the fact that the tractive effort due to grade depends upon the proportional length of train off the level track at the stations, and hence is a constantly increasing quantity until the entire train is on grade.

A grade of four per cent. has been chosen for the down-grade in a, and for both down and up grades in b; and energy consumption plotted in Fig. 3 for different lengths of grade.

Thus for a run of 2,000 feet in 75 seconds, the energy input with series parallel control is 40.75 watt hours per ton for a level track, which is reduced to 27.8 watt hours in curve a with a length of 500 feet, 4 per cent. grade and 22.6 watt hours per ton in c, with the same length of 4 per cent. grade, that is, with the same vertical fall.

A length of 500 feet of 4 per cent. grade calls for a vertical fall of 20 feet, which is not excessive in practice, hence by the use of a profile similar to b, Fig. 3, the energy consumption for a given run may be reduced as much as 40 to 50 per cent. from that required on a level track.

With proper proportioning of the gear ratio of the motor allowing some acceleration on the motor curve, this saving in energy consumption could even be exceeded, so that a rapid transit road, especially a tunnel road, properly laid out with an artificial profile, could operate with a very much less energy consumption than an existing surface road.

In conclusion it may be pointed out that the electric motor is eminently adapted to rapid transit service, owing to its ability to accelerate rapidly; and for tunnel work especially, it has no rival, adding to its high efficiency of operation its perfect immunity from smoke and gases.

Cost of Operating Electric Vehicles.

"L'Eclairage Electrique" states that the cost per kilometer of electrical vehicles at the time trials in Paris was about 0.5 franc, on the basis of a charge of 0.03 franc per k. w. hour, at which it is sold at the Place Clichy secteur station. Each vehicle expended current to the extent of $2\frac{1}{2}$ to $3\frac{1}{2}$ francs' worth on the route of 60 kilometers, the current consumed varying from 9.73 k. w. hours up to nearly 14 k. w. hours in different vehicles. Petroleum vehicles cost very much more. The minimum consumption of petroleum by the Peugeot vehicle was 13 liters per day. Petroleum cannot be bought for less than 0.6 franc per liter. Thus the journey cost would be 7.8 francs, or practically 78 pence for 39 miles, being practically 4 cents per mile—an amount heavy enough for two persons, being equal to a third-class railway fare. The expense in repairs, etc., of the electric accumulators has been given as 3 francs per day per vehicle. Added to the cost of the energy, this implies a cost of about 6 francs, as against 7.8 for petroleum.

TRAIN LIGHTING. It is figured that there are 6,000 railroad cars in Europe lighted by electricity, while the number in this country is sensibly rated at much less than 1,000. The European statistics seem very much open to doubt.

Columbia Electric Motor Carriages.

AMERICAN manufacturers at an early stage foresaw the demand for automobiles, and have gradually, but quietly, developed types and invented apparatus which now in their more perfected forms are being placed before the public. The

COLUMBIA MOTOR CARRIAGE, MARK III.

success attained by the manufacturers on this side may be judged by the fact that the Columbia motor carriages placed side by side with all the latest and best types of foreign makes at the late Paris Exhibition easily outranked and outsold them. Several of these carriages, manufactured by the Pope Manufacturing Co., Hartford, Conn., were shown at the recent New York Electrical Exhibition, where they attracted considerable attention. In our issue of May 26 we described the construction of these vehicles in great detail and pointed out many important improvements. Since that time, however, additional details have reached us which will doubtless prove of considerable interest:

STORAGE BATTERIES.—The storage batteries supplied with the carriages are of a type best adapted to meet the required conditions of greatest efficiency with the least weight consistent with long life and ability to stand a certain amount of abuse and neglect. They can be charged from any 110-volt direct current circuit. Under ordinary conditions, the process of charging the batteries from completely empty to completely full requires about three hours and is extremely simple. The batteries are assembled in such a way that the leakage of cur-

COLUMBIA MOTOR CARRIAGE, MARK IV.

rent is reduced to a minimum and, unless the current is used to run the carriage, they will remain charged for a considerable period. When the recharging of a carriage has been completed the current is automatically cut off, and the purchaser

relieved of all anxiety on account of waste of current. If the batteries are reasonably well treated or given the same relative care as the horse, they will drive the carriages over thirty miles on level roads on one charge, and on roads and streets of the average city quality and possessing such grades as are common in our New England cities, will average on each charge a mileage of over twenty-five. The batteries used will, with reasonable care, last for more than 5,000 complete discharges; this, of course, representing a life almost indefinitely long for ordinary uses.

It seldom happens, where the current is taken from wires connected with the city mains of central lighting stations, that the cost for each full charge exceeds 60 cents. As is well known, electric lighting and power companies usually base their prices for their output on the amount of current consumed, and when a user of a carriage also employs the same electric current for lighting his house, or for any other purpose, he can arrange to charge his carriage batteries at a cost extremely slight. It has been found that the average cost of running a Columbia carriage is one cent per mile for current when taken from a public station. It frequently happens that owners of these carriages possess their own private electric plants, and when this is the case, the cost is even less, and under favorable conditions is sometimes as low as one-quarter of a cent per mile.

MOTORS.—In the single seated phaetons of the Mark III pattern, illustrated herewith, as well as in the two-seated dos-a-dos Mark VI traps, also shown in the illustration, a single motor of a normal capacity of slightly over 2 h. p. is employed, and on the double-seated carriages of the Mark IV pattern, two

COLUMBIA MOTOR CARRIAGE, MARK VI.

motors each of 2 h. p. capacity are used. All motors are especially designed for their particular use, are light, strong, and compact, and in common with electric motors generally will respond to a demand for more than double their normal capacity, when they are called upon to do so. Although, in order to be water and dust proof, they are completely encased, that part of the covering over the commutator and brushes can be quickly removed for such inspection as may be occasionally necessary.

WHEELS.—In a motor carriage, the weight, the great strains in starting, and the other trying conditions which do not exist in a horse drawn vehicle, call for wheels especially adapted to meet especially exacting requirements. The wheels on these carriages are thoroughly constructed in every detail of steel and forgings on the same lines as bicycle wheels, although many times heavier and stronger, have tangent spokes, and are absolutely reliable and capable of resisting the peculiarly severe strains of motor vehicle use. The front wheels are 32 inches in diameter, and the rear or driving wheels 36 inches on all the patterns of the Columbia electric carriages.

The tires are pneumatic, 3 inches in diameter, and of a specially durable construction, being not readily puncturable under any probable conditions. They are provided with a corrugated or "herring-bone" tread, which prevents their slipping even on asphalt pavements in wet or wintry weather when the use of horses is dangerous.

BEARINGS.—Every mechanical refinement and all service-

able features of bicycle construction, as developed by the Pope Mfg. Co., have been embodied in the Columbia electric carriages. The wheels are fitted with ball bearings, which add considerably to the ease of running and economy of power. Ball bearings are also used wherever else in the vehicle they can be of possible benefit.

FRAMES.—The frames are of special steel tubing, manufactured and tested for this particular purpose. They are rigidly braced and extremely strong, although as light as possible. As is the case with all other steel material employed in these vehicles, the tubing was made to precise specifications of the same exacting nature as those set by the United States Government for the material it purchases.

SPEEDS.—The carriages are designed for an average maximum speed of slightly over twelve miles per hour on the level. There are also two lesser speeds, one of six and one of three miles per hour. As the legal limit in most cities is eight miles per hour, it would appear that the company have amply provided for all contingencies of ordinary use. Indeed, their experience has proven that one of their standard carriages possesses just the requisite range of speeds for all ordinary city and park riding, it being possible at any time to go ahead of or proceed slightly faster than most ordinary passenger carriages. All three of the speeds can be obtained backwards by a very simple manipulation. The great importance of this has been apparent to the owners of such carriages who have had occasion to go with them to the lower part of New York during the busy hours.

MANNER OF CONTROL.—In the left hand of the operator is held the controller handle, which is moved easily and with positive action through four positions from "stop" to full speed. It can be left continuously on any one of these positions, being fixed firmly until again moved by the operator.

The steering handle is held by the operator in his right hand, and the process of guiding the vehicle is much like steering a boat. The brake and reversing lever, mentioned later, are within easy reach of the left foot, and are immediately effective when put into operation.

BRAKE.—The brakes with which Columbia carriages are equipped are trustworthy. The principle of their use consists in the tightening of a band of bronze over an iron drum placed on the shaft of the driving wheels. This is done by a foot lever worked by the person running the carriage and is perfectly effective under any conditions.

RUNNING PLUG.—A very valuable feature in the carriages is what is termed the running plug. It consists of a small, aluminum, specially shaped key, which is inserted in the main circuit between the batteries and the motor, at a point where it is led up to a position convenient to the left hand of the operator. This plug, when removed, prevents the carriage from being started.

LAMPS.—Every Columbia carriage has four electric lamps, all controlled by switches within convenient reach of the driver's hand. There are provided the two lights, one on each side, commonly found on carriages. A head light is attached to the front of each vehicle just below the dash board, throwing a light forward so brightly that ordinary newspaper print can be read at a distance of over forty feet.

WARNING SIGNAL.—Each carriage is provided with an electric bell which is rung from a push button placed in the end of the controller handle at the left of the driver. It is sufficiently loud to accomplish its purpose, even where the din of traffic is excessive, without, however, being objectionable at any time.

WATTMETER.—A meter is provided, in sight of the operator, which shows at any time to what extent the supply of power in the batteries has been used. This meter is also used when charging the batteries and enables the attendant to know when they are charged.

UPHOLSTERY AND FINISH.—One of the chief objects which was kept in mind in the production of these electric vehicles was to avoid the awkward and cumbersome look and the resulting unpleasant impression conveyed by automobiles. The company therefore secured the co-operation of a firm of well known carriage makers. The bodies of the carriages are similar in design to the latest models now in vogue. The upholstery is of imported whipcord of absolutely the best quality. The cushions are stuffed only with the choicest curled hair. The coloring of the seat panels is in a dark rich green. The

bodies are absolutely black and the gears are painted to match the seat panels, picked out with just enough bright red to make them attractive, yet not loud. The most careful attention has been given to details, which are always necessary in the production of strictly high grade work.

The results of these efforts to produce a beautiful motor carriage is considered eminently satisfactory. The finish and upholstery are of the very highest order, and all the appointments are comparable to those of the most stylish park phaeton or Victoria.

WEIGHT.—The total weights of the vehicles vary from approximately 2,000 pounds in the smallest to 3,500 in the largest. For these weights the batteries are responsible for one-third.

HILL CLIMBING.—The Columbia carriages are able to take any ordinary city grades without difficulty, and can climb easily ascents possessing a rise of not over fifteen feet in each hundred. In cases, however, where a carriage is to be used in an abnormally hilly country, the company is prepared to equip it with a special low gear, which will enable it to climb hills possessing grades even steeper than 15 per cent. at a speed considerably more rapid than the gait which a horse would take in doing the same work.

PRICES OF VEHICLES AND BATTERIES.—For the three carriages shown in the cuts the prices are as follows, all f. o. b. Hartford, Conn.: Mark IV., \$3,000; Mark VI., \$2,750; Mark III., \$2,500. Extra storage batteries will be supplied for the following prices per set, ready for placing in the carriage and connecting up, prices f. o. b. Hartford, Conn.: Mark IV., \$525; Mark VI., \$425; Mark III., \$375. These figures make the storage battery compare most favorably with the horse in its relation to the carriage proper, and assist in disabusing the average mind of the confusion resulting from an attempt to compare what appears to be a carriage alone with a carriage and horses, harnesses and equipments, when in reality the first as it stands takes the place of the second with horses, accessories and equipment complete.

The Baldwin-Westinghouse Electric Mining Locomotives.

ON account of its extreme flexibility, permitting ready extension or change as mining conditions frequently require, electricity has been established as the most convenient and economical form of motive power for mine haulage. The compactness of the electric locomotive makes it perfectly adaptable to low and narrow entries; and, by reason of the absence of moving parts exposed to external injury, mechanism of the simplest possible character, and running parts readily accessible for replacement, the cost of maintenance is brought to a minimum.

The power for operating electric mine locomotives may conveniently be furnished from the same electric generating plant which supplies current for lighting and other mining work, and the same wires may be made to convey the current for all purposes, thus making a simple system of distribution and reducing the attendance to the minimum. These advantages were early recognized, and numerous types of mining locomotives were devised and tried. A number of these proved successful, but when it was announced a few years ago that the Baldwin Locomotive Works and the Westinghouse Electric and Manufacturing Company had joined forces and were going to manufacture electric mining locomotives, electrical and mining engineers expected with confidence a well designed and efficient machine. The extended experience of the Baldwin Locomotive Works in the manufacture of steam and compressed air mining locomotives assures careful design of the mechanical features of the locomotives, while the well known excellence of the electric railway apparatus of the Westinghouse Electric and Manufacturing Company guaranteed that the specially designed motors for these locomotives would embody the latest improvements in electrical practice.

After a number of years of experimenting with various types of locomotives, this powerful combination has recently brought out the machine illustrated in perspective in Fig. 1. The locomotive frame consists of heavy cast iron side and end pieces securely bolted together and kept square by machined joints and shoulders accurately fitted. These frame pieces are planed top, bottom and ends, to insure perfect accuracy in fitting up and interchangeability of parts. The pedestal caps are forgings

made to templet, and accurately fitted, so as to relieve the frame from breaking strains in case of severe shocks. The frame is placed outside of the wheels, thus allowing all possible space between wheel hubs to admit the greatest practicable width of motor. This feature is of much importance in obtaining the maximum power on narrow track gauges. Furthermore, this

with six speed changes, and is operated by handles for starting and reversing. The rheostat or "diverter" is of a non-combustible type, very compactly set up, and has large carrying capacity.

The trolley pole is specially designed for this service; it is reversible and can be placed in a socket in either side of the frame,

FIG. 1.—BALDWIN-WESTINGHOUSE ELECTRIC MINE LOCOMOTIVE.

construction permits of ready accessibility to the journal boxes, and protects all moving parts in case of derailment. Heavy planking with hinged doors is laid on the frames, thoroughly protecting all electrical parts, but permitting access for inspection. End bumpers and coupling hooks are provided in conformity with purchaser's requirements.

The journal boxes are of ample dimensions and have bronze bearings with oil cellars for sponging, as in steam locomotive practice. The brake apparatus, which is fitted to all wheels, is of simple design and of sufficient power to utilize the track adhesion due to the weight of the locomotive. The operating platform is placed at one end, and is compactly and conveniently arranged so that the motorman has all levers within reach without leaving the seat. The entire machine, with electrical apparatus, is supported on the journal boxes by helical springs, which prevent destructive pounding on the track and relieve the machinery from shock. The locomotive is driven by two spring supported motors, one geared to each axle by single reduction gearing running in oil lubrication in tight cases. These

and automatically adjusts itself to varying heights of trolley wire. It is thoroughly insulated to prevent shocks to the operator when being handled, and the current connections are made by insulated cable. The locomotive is provided with all necessary minor electrical fittings, such as fuses, lightning arrester and main switch and two electric headlights. All sizes are designed to run at a standard speed of eight miles per hour when developing their full load tractive effort. With light trains, requiring less than full load upon the motors, the speed of locomotive may be increased. When starting, the train is brought gradually up to full speed by means of the controller.

Fig. 2 shows a side view of the frame of the locomotive and having reference to the letters on this figure the standard sizes of the locomotives are as follows: There are five sizes ranging from 20 to 150 h. p.; the draw-bar pull on a straight level track from 900 to 6,500 pounds; on a 4 per cent. grade from 660 to 5,140 pounds. The minimum track gauge varies from 24 to 56½ inches; wheel base C from 24 to 36 inches; width 41 to 74 inches; length A 10 feet 4 inches to 13 feet 6 inches; height

FIG. 2.—SIDE VIEW OF BALDWIN-WESTINGHOUSE ELECTRIC MINE LOCOMOTIVE.

motors are designed especially for mining service and are of the four-pole, steel clad, enclosed railway type. The armature is of the iron clad type, the coils being held in slots below the surface and secured from displacement, as in the most approved railway practice.

The current controller is the latest rheostatic type, with magnetic blowout to prevent arcing at the contacts. It is provided

F 33 to 42 inches, and the weights ranging from 7,000 to 34,000 pounds.

A large number of these locomotives have already been installed, and judging from the satisfaction which they have given everywhere, it appears as if the Baldwin-Westinghouse locomotive meets admirably the difficult conditions presented by mine haulage.

The Eddy Electric Carriage Motor.

THUS far in spite of the limitations of the storage battery, the electric carriage has most successfully met the requirements. Careful investigation has shown that rarely does the daily distance traversed by the horses drawing city carriages, physicians' phaetons, hacks, hansoms, express and delivery wagons exceed twenty-five miles, and the average distance is much less than this. Without too great a weight of storage battery an electric carriage can easily accomplish this distance on one charge, and as it is clean, free from odor, practically noiseless, and easily handled, it has the advantage over other forms of propulsion, all of which lack one or more of these characteristics. It of course cannot, under existing conditions, pretend to be available for long distance work, but in its province is certainly a commercial success.

In order to attain the successful results reached, the manufacturers of the American carriages have had to call on the makers of storage batteries and electric motors for apparatus to meet the peculiarly severe requirements of the service, and

adapted to meet the requirements as above set forth. It is designed for an average current input of 20 amperes, and with this current and at 75 volts will run at 1,000 r. p. m. It will carry this current continuously without dangerous heating, and 40 amperes or 100 per cent. overload for twenty minutes without a rise in temperature exceeding 75 degrees Cent. above the air. It will also withstand loads up to 100 amperes for short periods. This capacity has been found to be ample for driving a two-seated carriage weighing about 1,800 pounds at a speed of about twelve miles an hour over good macadam roads, and is ample for ascending any hills likely to be encountered. For four-seated carriages two motors of this size are used. From 75 to 80 volts seems to be a convenient pressure at which to rate motors for this work, as this is about the minimum e. m. f. of discharge for a storage battery, at normal current, which may be charged from a 110-volt circuit direct. The speed of 1,000 r. p. m. is sufficiently low to permit of convenient gearing with the axle of the carriage.

In order to secure as light weight as possible, the motor is made with a field frame of Norway wrought iron forged to a

THE EDDY ELECTRIC CARRIAGE MOTOR.

consequently new types have had to be designed for this work.

The conditions under which the motor or motors of an electric vehicle operate are similar to those governing in street car work. The ratio, however, between maximum load and average load is much greater than with the trolley car, for every kind of roadbed may be found from sheet asphalt to thick mud, and any grade that a horse can climb must be ascended by the electric carriage. The motor must therefore have great capacity above that at which it is normally expected to run.

For the economy of the stored energy the motor must have as high a commercial efficiency at the average load as possible, and this efficiency at heavy overloads must be maintained in order to minimize the strain on the battery. The efficiency of the motor at loads less than the average is not of great importance if the battery is properly proportioned for the work. Such loads occur when the carriage is on a declivity, and at these times the current drawn from the battery is very light.

It is of course desirable that the motor shall be of as little weight and small dimensions as is permitted by the power and speed required. It must also above all things be "fool proof," that is, must be so constructed as to require no attention whatever and to withstand all kinds of abuse.

The illustration shows a typical electric carriage motor

rectangular shape and having two salient and two consequent poles. To this frame are bolted at either end cast aluminum casings, which support the rings for ball or roller bearings. The armature is mounted on a hollow shaft so that it may be suspended concentrically with the main axle of the conveyance. The armature winding consists of machine formed coils laid in slots cut in the surface of the laminated core. This form of construction is extremely light, but should only be used where the method of motor suspension supports the bearings directly and thus relieves the strain of the gears on the aluminum casings. The motor above described weighs complete but 128 pounds, a surprisingly low result when its power and efficiency are considered.

The appended curves show the speed, torque and efficiency of one of these motors as found from an actual test with a Prony brake. The efficiency curve is the most interesting, perhaps, as upon it depends the range of operation of the carriage. It is noticed that the efficiency rises almost in proportion to the current until the normal load is reached, and from that point maintains a high reading up to 35 amperes or 75 per cent. overload, dropping so gradually after this that it is still remarkably high at 150 per cent. overload. As already stated, the maintenance of high efficiency from normal average load to heavy overloads is extremely desirable. It can only be obtained on

such small machines by making exceptional efforts to reduce the internal resistance as low as possible. Extra care must be taken not only with the windings, but in all contacts. Especially is this true with the brushes and brush holders, and in the motor from which the above data was taken the holders were designed so that current was drawn from the self-feeding brushes without reliance at all on the sliding contact. Ball or roller bearings and low armature loss also contribute to the high efficiency attained.

As the motor is suspended usually under the carriage frame it must be, of course, dust and water proof. It is subjected also

CURVES, OF SPEED, TORQUE AND EFFICIENCY, EDDY CARRIAGE MOTOR.

to exceptionally severe jars and vibration, which tend to abrade and destroy insulation which under ordinary circumstances would be perfectly satisfactory. This brings before the manufacturer a problem, not easily solved even by those having had experience with railway work.

The motor which has been illustrated and from which the data is taken is one manufactured by the Eddy Electric Mfg. Co., a concern that has had considerable experience with this class of work, and which has furnished motors of different types and sizes for the various electric carriage makers of the country.

A Big Prize for an Automobile Accumulator.

At the last meeting of the committee of the French Automobile Club a letter which had been received from a firm of accumulator manufacturers was read. In this letter the firm, whose name was not made public, offered to set aside a sum of \$5,000, to be given to the maker of any accumulator which could be proved to be better than their own. The committee resolved to write to the firm in question, stating that they were willing to accept the \$5,000, and to make it a prize for the best accumulator in the secondary-battery competition, which it is proposed to hold next winter.

HAWAIIAN TROLLEYS will probably be put in by some Buffalo men connected with the Buffalo Railway Co., who are after the Honolulu franchise.

Who Shall Pay the Telegraph Tax?

The Illinois Manufacturers' Association, Chicago, will bring a test case against the telegraph companies to decide whether the companies or the customers shall be required to furnish the revenue stamps affixed to telegrams. Levy Mayer, counsel for the Manufacturers' Association, will begin the case against one of the telegraph companies as soon as a similar case against the United States Express Company has been decided.

The North Carolina Railway Commission has taken action on complaints against the Southern Express Company and Western Union Telegraph Company for exacting and collecting from shippers and senders of messages a higher rate than that fixed and approved by the commission, by forcing the payment by shippers and senders of the revenue tax stamps. The express company and telegraph company are cited to appear July 29 and show cause why the penalties for overcharges should not be enforced. They are also ordered to furnish to the commission sworn statements of the number of messages or shipments upon which overcharges have been made between July 1 and July 29.

KANSAS CITY, MO.—A great deal of angry comment is made because in the case of a message conveying the news of a sudden death, the telegraph operator refused to take the message on the ground that it did not bear the 1 cent revenue stamp.

Pacific Cable Schemes.

A London special dispatch of July 20 says: "The Pacific cable is again moving. Hon. Mr. Mulock, Canadian Postmaster General, yesterday met the Australian agents general, and went fully into the best means of bringing the project to a conclusion, especially in view of the probability that unless the British cable is shortly laid, the Pacific may be crossed by non-British telegraphs, namely, a cable from San Francisco to Hawaii, with extensions to New Caledonia, connecting with the French cable to Australia. The greatest obstacle to the British project is just the permanent officialdom which Mr. Chamberlain had to overthrow before imperial penny postage could be carried."

The Telephone and the Hotels.

A well known landlord of Boston and New York is quoted, says the Boston "Advertiser" as telling mournfully about an instance in which a company of business men in this city who deemed it necessary that they should all go in a body to St. Louis to confer with a number of business men there upon important matters, discovered to their own great surprise that at an expense of just \$11.50 they were able to transact all their business by long distance telephone; and thus save the difference between that small sum and at least \$300, which would have been required for traveling expenses. Besides, there was a saving of nearly a week's time for each of the Boston men concerned.

Yes, there is no doubt that this sort of thing is increasing, and that it is correspondingly diminishing the profits of landlords and railway companies. But let our genial Boston boniface take courage. The long distance telephone will not altogether take the place of the old method, of extending the glad hand and sitting down to talk over matters face to face. For instance, a Boston business man cannot very well say to a St. Louis business man, by long distance telephone, "What's yours?"

Government Controls the Santiago Cable.

The West Indian and Panama Telegraph Company has sent the following notice to the Western Union Telegraph Company's central cable office: "The American Government has taken possession of the cables at Santiago de Cuba, and no communication via Jamaica and Santiago will be allowed until further notice."

A special dispatch from Washington of July 20, intimates also that Governor Blanco cannot do any more of his tall lying for foreign consumption. It says: "Gen. A. W. Greely, Chief Signal Officer, cabled instructions two days ago to his officers in Santiago to seal up and place a guard over the three cable lines connecting Santiago with Cienfuegos, whence by a land line communication is established with Havana. To-day Gen. Greely was informed that his orders had been carried into effect. The closing of the Cienfuegos cables absolutely isolates Havana and Gen. Blanco from Madrid. Blanco's only means of communicating with the Government at Madrid now is by the Key West cable, which is under the strictest censorship by the Government of the United States. As a result of the sealing of the Santiago-Cienfuegos cables, several cipher dispatches passing between Gen. Blanco and the Spanish Government drifted into this country to-day. It is scarcely necessary to say that they did not reach their destination. The final cutting off of communication between Blanco and his home Government is a source of great satisfaction to the Administration, and is another laurel for Gen. Greely's active vigilance."

The Telephone Toll Tax.

Mr. Charles Flowers, of the Independent Detroit Telephone Co. says: "People probably do not know that the war tax falls more heavily upon the Independent Telephone Company than upon the Bell concern, but that is a fact. The law puts a one-cent tax upon each message costing 15 cents or more. Now, none of our messages cost more than 25 cents, because the Detroit Telephone Company and its branches do no business outside of the State of Michigan. The Bell Company handles messages running anywhere from 10 cents up to that number of dollars, but they pay only the one cent, no matter how much the messages to New York or Boston may net them. You see, on the basis of our dearest message, 25 cents, we pay a 4 per cent. tax, which is rather heavy. And we pay it, too. We don't make our patrons pay the tax."

Report Against Municipal Telephony at Columbus, O.

The special committee appointed by the Columbus, O., City Council to investigate the advisability of establishing a municipal telephone system in Columbus has made a majority report and asked that the committee be discharged and that for the present the Council refuse to further consider the subject.

When the committee was appointed it was at the request of Mr. Marshall, and was instructed to investigate the municipal ownership system and report to the Council whether or not in their judgment it would be wise at this time to attempt to put the system into operation in this city. When the committee reported they came in with a majority and a minority report by Mr. Marshall, who wants more data. The former was submitted by A. E. Evans and F. W. Wiechers, and was adopted by the Council. They stated in the report that the committee had visited Toledo and Detroit and there studied the systems in use and came to the conclusion when they had finished that this city wanted nothing of that sort. They said in Toledo they had found that the system was in such bad repair that they would not admit visitors to their exchange room. They said in the other places they found the same thing. Everywhere the Union Bell Telephone Company had the better plant and the work of the smaller ones was not at all satisfactory. They said also that the people are dissatisfied with having the two systems, as it in almost every case necessitates having both of them in the one place. They said in their investigations all through the country they had the idea that two lines were not at all popular and then it was almost now an impossibility for them to have a communication with another city when they had the city owning all of the line in its bounds. Another thing, they said, was bothersome, and that was that the laws of the State would not permit them now to have the municipal ownership of the plant, or at least there is no provision for that in the laws of the State. There was a resolution introduced into the Legislature at the last session recommending the laws be changed so as to permit that, but it was voted down by a very great majority. They recommended that the Council leave that matter for the present until there should be a new Legislature. They further recommended the director of law should

communicate with the Legislature with reference to having a law passed that would permit the cities of the State to establish a system of that sort. They referred to the statute that provided for all of the improvements in a city, such as sewers, lighting and waterworks, but said the telephone was not included.

Municipal Telegraph Chiefs to Meet.

Preparations for the annual convention of the Association of Chiefs and Superintendents of Fire and Police Telegraph and Municipal Telegraph Systems, which is to take place in Elmira, N. Y., on August 9 and 10, have been made by Will. Y. Ellett, the president of the organization, who is in charge of the municipal telegraph and telephone system of Elmira. A number of papers on subjects of interest to the organization will be read, and Mr. Ellett says that the people of Elmira will hospitably entertain the visitors. The wish has been expressed that the superintendents and chiefs bring their wives. There will be a trolley trip to Horseheads, an interesting suburb, a dinner at a quaint little cottage at that place, a trip to Watkins Glen and a dinner at the hotel there.

Edward Dexter Brown.

IT is with deep regret that we chronicle the death of Corporal Edward Dexter Brown, of Troop C, National Guard of New York. Mr. Brown was widely and well known in the electrical fraternity. Born in Reading, Mass., August 29, 1868, and educated in the public schools of that place, he entered the Massachusetts Institute of Technology and graduated in the class of '90 with the degree of Bachelor of Science. Shortly after graduation he entered the Engineering Department of the American Bell Telephone Co., and distinguished himself while there by his fertility of ideas and close application to business.

In September, 1891, he entered the employ of the American Telephone and Telegraph Co. (Long Distance Co.), as a special inspector, passing thereafter through the positions of New York manager and district inspector to that of the general inspector, a position which he held at the time of his resignation to enter the service of the United States Government. Mr. Brown was one of the most expert telephonists of his time, and his personality will be recognized in many branches of the art for a long time to come.

His connection with various societies will be greatly missed. He was a member of the American Institute of Electrical Engineers, the M. I. T. Society of New York (a member of its executive committee), the Brooklyn Institute of Arts and Sciences, M. I. T. Alumni Association, Crescent Athletic Club, Brooklyn Reform Club, and president of the Telephone Society of New York.

In 1897 Mr. Brown enlisted in Troop C, National Guard, State of New York, as a private. He volunteered on the first call and was mustered into the service of the United States on May 22, 1898. He was made a corporal shortly before his troop left for Camp Alger. On June 29 last he was stricken with typhoid fever and taken to the post hospital at Fort Myer, where he died on July 2. He leaves a widowed mother, a brother and a sister.

John Mason Jackson.

A SPECIAL dispatch from Honolulu says: John Mason Jackson, of Chicago, who was superintendent of the Western Electric Company, of Chicago, is dead. In search for health he went to Hawaii six months ago with Dr. Rozell. He died at the home of Dr. J. S. McGrew, and the remains were interred in Uunanu Cemetery. The Chicagoan was suffering from nervous prostration brought on by overwork, and had nearly regained his health, when he was stricken with diphtheria. He was 39 years of age, and a personal friend of President Harper of the University of Chicago.

Vol. XXVI. NEW YORK, JULY 28, 1898. No. 534.

The Counter E. M. F. Method of Car Motor Regulation.

IN our last issue considerable space was devoted to the description of the Henry "Regenerative" controller for electric cars, and it was editorially compared with the system most in use at the present time, the series-parallel. The advantages claimed for the Henry system were so numerous and alluring that the opinion was expressed that tests of it on a large scale would be looked forward to with a great deal of interest by the profession. The radical departure from series to shunt motors and the regulation of the speed by means of the fields instead of the armature, as well as the absence of arc-extinguishing devices, are all features which speak favorably for the proposed system. However, other methods for motor control have been proposed in the past, such as the commutated field method, which consists in dividing the field into sections and changing the e. m. f. at the armature terminals; and the rheostat method in which rheostats are placed in series with the motors, the motors being placed in parallel at the start. These methods, however, have not survived, and the series-parallel controller reigns supreme in this country at the present time. It is economical in operation, gives perfect control of the speed of the car and an easy variation over a wide range; it permits the running of cars in crowded thoroughfares where slow speed is imperative and stops are frequent; it enables the cars to be run at high speeds as well; it does not necessitate frequent repairs and is not very expensive. Its disadvantages, however, are the possibility of one motor racing when the controller is in the series position and the current is applied suddenly; its unfitness to be applied to many motors on account of the unequal division of work; the liability of rushing the controller ahead of the car acceleration and the waste in all connections where an intermediate condition would suffice as well as in the use of resistances. Most of these disadvantages are claimed to be overcome by a system of control devised by Mr. Rudolph M. Hunter. This system requires no resistances and controls the speed of the motors by delivering to them a current of constant potential, varying the current, and interposing a varying counter e. m. f. independent of the counter e. m. f. of the motor in advance of changes in the speed of the motor. This is done in such proportion that the sum of the counter e. m. f. of the motor and the independent e. m. f. shall bear such relation to the initial e. m. f. of the current of constant potential as will offer the requisite resistance to the current desired. Mr. Hunter's invention is claimed to be of great importance in the operation of large motor cars, locomotives, or trains where the motor elements may develop 1,000 h. p. or more. No regulators proper are placed on the passenger cars, but, instead, the forward part of the train is provided with what may be

termed a "pilot" car upon which are arranged the necessary controlling devices for simultaneously regulating the current to all the motors of the train. The regulator on the pilot car is a counter e. m. f. generator whose counter e. m. f. is made greater or less to oppose the initial e. m. f. to a varying degree. This generator can be made of a small number of coils of large size and be rotated at a very high speed. The main current then is passed through the generator, thence through all of the field magnets of the motors, thence back to the pilot car and through one part of a reversing switch, thence back through the armatures of all the motors on the cars, and finally returned to the other terminal of the reversing switch on the pilot car and back into the line. The regulator consists of two parts, a counter e. m. f. generator and a hand-switch device for varying the counter e. m. f. at will.

The pilot car which, as will be seen, is self-propelling, is enabled to shift itself in making up trains or for conveying itself from one place to another when detached from a train. The principal claims made by Mr. Hunter for this ingenious but complicated method are that his system permits the control of any number of cars in the simplest manner possible and with the least loss of electrical energy. Also that the wiring on a train is reduced to a minimum so as not only to reduce the expense but also the liability of derangement. These claims are certainly worthy of consideration, as are also those of Mr. Henry, and it appears as if the wasteful and not otherwise altogether satisfactory series-parallel controller may soon find a rival in one or both of the above methods, or even in some other. It may be earnestly hoped that they will be thoroughly tested at an early date. Many good things go wrong for unsuspected reasons foredooming them to failure.

The Present Status of Electro-Dentistry.

WHILE it may be claimed that electro-therapeutics or the treatment of diseases by means of the electric current is of very early origin, it must be admitted that it received a marvellous impetus during the decade just coming to a close. This may be ascribed not so much to the perfection of electro-medical apparatus as to the proper electrical training of those engaged in surgical and medical practice. This in turn led to a correct study of the electrical effects on the human system and the laying down of certain definite laws governing the application of electricity. Wideawake to the possibilities of this new agent and its wonderful curative properties, the medical practitioners were ready to co-operate with the manufacturers of electro-medical apparatus in the design of instruments and appliances best suited for their requirements. Of still later origin, however, is the application of the electric current to dental surgery, where it had been employed but little until two years ago for the driving of mechanisms, cauterization, the translumination of soft tissue, the illumination of cavities, and other useful operations. It was at that time that Mr. Geo. H. Guy, in an able address before the N. J. State Dental Society, foreshadowed the lines which have put men to work and inspired the confidence of the dental practitioners in the usefulness of the electric current for other processes, such as implantation and sterilization, as well as the applicability of the Röntgen rays.

His words seem to have borne fruit, if one is to judge from the numerous electrical appliances exhibited at the twenty-eighth annual convention of the New Jersey State Dental Society, held at Asbury Park, July 20, 21 and 22, and described in another column. The members of this society deserve special mention for their early recognition of the value of the electric current for dental surgery by their papers and earnest discussions of subjects relating to electro-dentistry. But while several of these men have worked quietly, successfully and conscientiously, it must be admitted that the dental profession in general are still keeping somewhat shy of electricity for fear that they may not apply it properly. This has naturally restricted progress for the past year or two. The remedy for this unfortunate state of affairs must be found in embodying in the curriculums of our colleges of dentistry a thorough course in electro-dentistry, a correct understanding of the laws of application of electricity to dental surgery, a willingness on the part of practicing dentists to adopt the new methods, and the co-operation of manufacturers and practitioners to produce the most convenient and useful apparatus for their application. That this latter fact is being accomplished was evidenced by the numerous apparatus exhibited at the convention by various firms.

Regarding Röntgen rays it should be said that they have be-

come of great value to dentists, as by their means a permanent image of the teeth, gums and jaw can be obtained, depending upon the difference in the transparency of these parts to the rays. By their means not alone can an outline of the teeth be obtained, and the connection of their roots with the jaw, but also the canals, relative location of fillings and an outline of the gums. The use of the electric current for dental purposes seems to be nearly limitless, for, as Mr. Guy pointed out two years ago, among many other applications, "any drug that has been previously used without electricity within the mouth to produce specific effect, may now be electrically used with tenfold its former power for good." And thus we see a very fruitful field still open for thoughtful work, one which must be productive of a great deal of good to the dental profession in particular and suffering humanity in general.

Current Density as a Factor in Copper Refining.

THE recollection of the mystery which surrounded the electrolytic copper refining industry, as it existed fifteen or twenty years ago, may now well raise a smile among those who in these days handle thousands of tons of copper matte monthly. The secret of success was supposed to rest safely with a few German establishments, and with one well known gold and silver refining concern in this country. Of course there was no secret in the real sense of the word; but, nevertheless, besides this supposed barrier, there were substantial deterrents to the undertaking of electrolytic refining work and principal among these was the great cost of the plant and particularly the long period of time during which a large stock of metal remains unproductive of interest while undergoing the process.

It is perhaps to the great reduction in the latter item that the notable increase in electrolytic metal refining work is attributable. This is well brought out in a very able review of the situation by Mr. Titus Ulke appearing in the "Engineering and Mining Journal." It was not at all uncommon ten years ago for copper refiners to stock their tanks with 75 to 100 times as much copper as was daily produced in regular work. This enormous disparity has been gradually reduced so that to-day only from one-fourth to one-fifth that amount is required, or an average of 15 to 20 tons per ton of output.

For the ultimate cause of this marked improvement we must look to the method of handling the baths and especially to the higher current densities now made practicable. Whereas formerly currents of only 2 to 4 amperes per square foot were thought permissible, to-day current densities of from 15 to 20 amperes are employed in some establishments, and the end is not yet in sight.

The conclusion reached by Mr. Ulke is that the average proportion between the total copper "in process of treatment" and the yearly capacity (measured by output) of our electrolytic copper works is now about 4 per cent. as against two or three times as much formerly, and that the average proportion is going to decline still lower within the next year or two. These are interesting developments, and it is safe to say that with the water powers now being rapidly developed in the United States we shall see still further increases in the electrical metal refining industries.

Municipal Street Railways at Glasgow.

IT will be remembered that, until it was hunted to earth and killed, a very absurd statement was in general circulation in this country to the effect that Glasgow was able to do without local taxation, to pay salaries of all local officials, because of the profits from its municipal street railways. Anything more preposterous it would be hard to conceive, but the story was swallowed bodily by all sorts of municipalists here and was also used everywhere as an argument for municipal ownership. We pointed out at the time, how ridiculous the whole business was; various street railway officials here investigated and exposed the fallacy; and at last the city authorities came out with an unqualified official denial, on account of the innumerable inquiries they were receiving on the subject.

We have now the last Glasgow city tramway figures before us, and are forced once again to smile at the hugeness of the joke that could attribute to such a system the possibility of earning profit enough to pay the salaries of all the officials of the second city in the United Kingdom. The system carried only 106,000,000 passengers, and 35 per cent. of these paid only one-cent fares, for the shortest ride. The gross receipts were only \$1,946,080, and the profit is put down at slightly over \$500,000.

Off this profit, however, comes \$305,000 for charges, leaving only \$200,000 for permanent way renewal and general reserve fund. This is not all, however. The city has 4,267 car horses and 385 horse cars, but should it adopt mechanical traction, as proposed, that investment would have to be written off at a terrible depreciation, as we all know who have witnessed the change in this country. Thus, as London "Engineering" remarks in its review of the balance sheet: "The balance of £100,000 of revenue over working expenses is more or less illusory." Of course it is; and the further statement is not less sensible: "It can scarcely be held that the tramways have yielded a substantial profit to the city as yet." It must be borne in mind, however, that, according to the London "Chronicle," the policy of the tramway department "is not to accumulate profits in aid of the rates, but to build up a fine service, both cheap and efficient." At present, we can say from personal experience and observation, the service is neither cheap nor efficient. One-cent fares for short runs prove nothing, and the population of Glasgow, lacking such a service as our large corporations give, enabling a person to travel ten and fifteen miles comfortably in fine cars for five cents, remains one of the most congested on the face of the earth. Incidentally we note that the city is pushing its municipal socialism a bit further by building its own cars. Why doesn't it build its own engine and dynamos? Why not make its own rails?

Presentation to the Volunteer Engineer Corps.

THE Engineers' Club, of this city, has offered to the first of the three regiments of Volunteer Engineers, under Col. Eugene Griffin, a stand of colors, to be paid for out of the club's treasury at an approximate cost of \$500. The offer has been accepted with warm appreciation, and has led to so many expressions of approval and interest that it is now proposed to make this episode a general engineering function of interest to all the technical societies, the presidents of three of which have expressed their cordial co-operation. The idea now is to present the brigade of three regiments at least one portable search-light equipment for use on the battlefield and in general work in relieving the wounded, bridge building, road making, etc. Such an equipment, in self contained units will cost about \$3,000, and is a thing for which no Government appropriation is available.

Subscriptions will now be received in any amounts, from \$1 up; and we hope the response from electrical engineers will be large, in view of the fact that so many members of the profession are in the corps, and also that the apparatus is electrical in its nature. The subscriptions should be sent in immediately as the first regiment is likely to be ordered to the front at any moment. The committee, comprising President John Thomson and other members of the Engineers' Club, has its headquarters there, 374 Fifth avenue, this city, and Mr. S. W. Baldwin is treasurer of the fund. We join with the committee in the wish that "a sum will be realized which will enable it to give fitting expression by material evidence, that the good will and moral force of the non-combatant engineers of America follow their active representatives at the front."

The Age of Automobiles.

IT will be noted that a respectable portion of our space is this week, and from time to time, occupied by articles and data relating to automobiles. This is but a sign of the slow, steady advance of the subject into the arena of practical technics, and of the coming supremacy of electrical vehicles for the major part of the work. But we do seem a trifle behind date in this country, when the fact is noted that at the recent exhibition in Paris no fewer than 750 automobile vehicles of the carriage type were shown, and that of these 120 were of the light chaise type. It may be questioned whether 150 carriages all told, have yet been built here. This may not be altogether a misfortune, for there are indications that the manufacturers, who come chiefly from the bicycle field, are rapidly settling down to electricity to the exclusion of other motive powers; and that the latest types of carriages built here compare more than favorably with those put forward as the best examples of the automobile art as practiced abroad. We are told, as an illustration of the situation in France, that a recent parade along the streets of Paris left the thoroughfares in need of purification, while many of the spectators were driven away by the stench of the petroleum. France has given its efforts chiefly to oil carriages, but may not have much to show for its pains after all, when the automobile industry at last gets down to its permanent basis.

New Lamps of the Sterling Arc Lamp Co.

IN the construction of modern arc lamps, no features necessitate such important consideration as simplicity of design and operation. The lamp therefore that most perfectly represents this ideal must be acknowledged the acme of arc lamp construction. This is the claim made by the Sterling Arc Lamp Company for their so-called "universal mechanism," it being, with slight detail modifications, the same in all their lamps, whether employed for alternating, direct multiple, series or railway circuits.

In a recent visit which we paid to the company's shop, their general sales manager, Mr. R. J. Randolph, very interestingly described to us some of the novel features of the Sterling lamp.

The regulating mechanism is of a new clutch chain feed type. The upper carbon holder consists of a cross-bar sliding between the two frame rods, with a carbon clamp centrally attached. Immediately above, the feed chain is connected and passes thence over the toothed clutch pulley in the mechanism. The chain is kept taut by means of a small weight attached to the other end and moving in one of the hollow frame rods.

In renewing the carbons, it is simply necessary to unscrew

operates on a pivoted clutch or brake bar causing the chain pulley to be gripped by the clutch member, turned the necessary distance, and carrying the carbon correspondingly. This clutch pulley is practically the complete regulating mechanism in all of the Sterling lamps. The inner globe is supported in a cup-like metal holder, fastened to the lower end of the frame rods. This support also serves as the clamp for the lower carbon. The inner globe is simply set in the holder and held in position by means of a cross-bar and cap, sliding between the two frame rods, and suitably held down upon the top of the enclosing globe, so that the latter is firmly and securely clamped in position, but can easily be removed by simply raising this cap-bar. In the construction of the globe cap forming part of this bar no moving parts whatever are used. It is claimed that

D. C. Cons. Pot. Lamp.

Cons. Cur. Series Lamp.

Style. D.

FIGS. 1, 2, 3 AND 4.—NEW STERLING ARC LAMPS.

the outer globe-holding cup at the bottom of the lower carbon holder, and then, by loosening the screws of the upper and lower clamps, the carbons are readily passed through the hollow lower holder, and new carbons inserted without removing or in any way disturbing the globe. The upper carbon is also readily removable owing to the flexible feed chain support. This chain is not used for current carrying, but a separate conductor serves for this purpose.

The movement of the feed chain and its attached upper carbon is controlled by the previously mentioned clutch pulley over which the chain passes. This pulley is suitably pivoted in a projection from the mechanism base, and the control magnet

owing to the construction of the upper sliding-bar carbon holder, perfect alignment is always maintained without the use of auxiliary mechanism in the globe cap.

THE CONSTANT POTENTIAL LAMP burns singly on 110-120 volt circuits, using about $4\frac{1}{2}$ to 5 amperes and 80 volts. The clutch mechanism consists of a chain brake around the feed chain pulley, and is attached to the operating bar, so that movement is imparted to both ends of the chain when the bar is actuated. This clutch or brake chain operates as a bank brake with both ends movable. By means of this arrangement it is insisted no motion whatever of the regulating cores is lost, as the slightest movement of the latter

grips the feed chain pulley and any further movement is imparted to the carbons. The lamp is adjusted by means of a stop pin regulating the movement of the brake chain bar. No springs are used.

THE STERLING ALTERNATING LAMP burns singly on 100-120 volts at 60 or 125 cycles frequency, using 6 amperes and about 70 volts, and burns from 80 to 100 hours with one trimming. One of the claims made for this lamp is that it consumes only 425-450 watts. A regulating reactive coil on the lamp is so arranged, that by changing the connections on the coil the lamp may be adjusted to any frequency and voltage. The regulating coils are double series, connected with reactive coil, and acting on double laminated iron cores attached to the bar. Coil spools and other metal parts adjacent to the coils are of non-metallic material. The switch for opening the circuit is on top of the lamp.

The clutch mechanism is the same as in the constant current series lamp, it being claimed that by reason of the particular delicacy of this mechanism and the absence of lost motion, the carbons are fed together without the usual jump and burn without flicker.

What appears to be a decided departure and novelty is that embodied in the Sterling enclosed series lamp. While the mechanism is substantially the same as that already described, the clutch wheel parts are slightly modified to meet the extremely hard usage to which this class of lamps is at times subjected. The feed chain wheel is clutched by a novel form of clutch device, which works similarly to the double acting chain brake already described. The regulating mechanism is differential, consisting of series and shunt double coils acting on solid cores connected to the clutch bar.

The cutout is operated by the end of the clutch bar when the carbons are all fed. This cutout switch seems to be particularly substantial, being, in fact, a well made double pole knife switch, cutting in a low resistance loop around the lamp terminals.

No springs are used for adjustment, the lamps being regulated by means of a stop pin as in the multiple lamps. The lamp switch or line cutout is a decidedly new feature which is claimed to possess advantages found in no other similar device, as it altogether eliminates all possibility of danger to the lamp trimmer. This switch is in a separate case, which is hung from the supporting hook, and consists of a double centrally pivoted knife blade switch operated by a suitable handle, so that the lamp is entirely disconnected from the line and the current is not shunted through the lamp. The line wire enters this switch box, being properly looped, and the terminals from the switch to the lamps project through the bottom of the switch base in the form of two heavy insulated brass hooks.

On top of the lamp hood are two corresponding hooks, and to connect the lamp to the terminals from the line projecting through the switch base it is simply necessary to engage the hooks on the lamp with those from the bottom of the switch box. This is done by a rotary movement, and to facilitate this operation, and also to prevent any swinging of the lamp and to hold the hooks firmly together, a centrally placed pin from the top of the lamp hood enters an aperture in a projected stud from the switch box base. This pin serves both as a pivot and a steadying pin or bolt. Many advantages are claimed for this "hanger cutout," as it is called to distinguish it from the ordinary cutout boards.

The company also makes an open air series lamp similar to the foregoing. The power and railway circuit lamps employ the differentially controlled mechanism as in the series constant current lamps. They burn two in series on 220 volts, and five in series on 500 volts, taking $4\frac{1}{2}$ to 5 amperes. Resistance is provided on top of each lamp, or one resistance in a fireproof box for the entire group.

A distinctive feature of the lamp is that all parts of the mechanism are either enamelled, nicked or japanned.

The company is now placing its agencies throughout the country, a number of very desirable territories having recently been allotted in the West.

FARGO, DAK. Gen. Hughes and Sons have accepted the electric light franchise recently granted them by the city council over the mayor's veto, and having secured a site along the Northern Pacific right of way will have their plant in operation by the end of September.

Electricity at the 28th Annual Meeting of the New Jersey State Dental Society, at Asbury Park, N. J.

THE twenty-eighth annual convention of the New Jersey State Dental Society was held July 20, 21 and 22 at Asbury Park, N. J. Although the attendance of members of this thriving and influential body was somewhat affected—as so many conventions have been this season—by war conditions, some excellent papers were read, and preparations were made for a year of special activity. There was an exhibition of dental specialties, many of which were electrical.

The S. S. White Dental Mfg. Co., 1 Union Square, New York, had, as usual, a comprehensive and effective exhibit. One of its popular features was a motor stand outfit designed for use on the 110-volt direct current. It can be used on circuits having voltages from 100 to 120, or on a 220-volt power circuit with an extra special reducing resistance. It is not intended for employment with alternating current, primary or secondary batteries. It meets the needs of dentists by providing an efficient, compact, and convenient apparatus of a wide range of adaptability. The apparatus consists of the S. S. White dental motor, No. 2, an iron stand with a mahogany top, supporting a fire-proof, speed regulating resistance in an iron case, and an electro magnetic clutch on a countershaft, supported on front of the stand, and a governing treadle connected to it by cable. The motor is enclosed in a glass case to protect it from dust, and the stand is mounted on wheels to facilitate its ready movement from one position to another. The special motor with this outfit has an extra pair of brushes, and collecting rings for use with transformer. The new S. S. White transformer, which is connected with the motor outfit, or to a special treadle rheostat outfit, furnishes a low-volt alternating current for operating electric mallet, mouth-lamp, hot-air syringe and cautery. The transformer, wall-switch, fuse plugs and connecting plate are enclosed in a mahogany case, $7\frac{1}{4}$ inches wide, $13\frac{3}{8}$ inches high, and $6\frac{3}{4}$ inches deep, which is fastened to the wall near the chair of the operator. When the door is closed, the apparatus is out of sight, and therefore cannot be tampered with.

About two years ago dentists began to take a great interest in the question of cataphoresis, and since that time the leading firms of electro-dental manufacture have devoted much attention to the devising of suitable instruments for cataphoric work. The cataphoric outfit found in this exhibit contains some excellent points. The controller consists of a polished wood cylindrical case with black enameled slate top, $5\frac{1}{2}$ inches in diameter and $1\frac{1}{2}$ inches high. The regulating wheel is raised above this 1 inch. Four cone-socket connecting posts receive the cords from the battery and electrodes, and a switch on the side of the case cuts off the entire current. The regulating wheel is $2\frac{3}{8}$ inches in diameter, and contains the scale protected by a crystal cover. The apparatus is well under control and the adjustment is exceedingly accurate.

This firm have also bestowed particular care on the construction of mouth lamps for dental work. One form of lamp they exhibited is highly recommended by dentists. It lights up the teeth and gums so strongly that any cavity of decay or unsuspected dead pulp, or even the slightest thickening of the tissues, which is precursor of decay, is unerringly detected. Illumined by this lamp, while sound teeth will appear translucent without variations in texture, a dead tooth will be opaque, even when its color gives no indication to ordinary observation; and a cavity of decay of any foreign substance will show as plainly as a spot on a window pane. For the examination of posterior cavities a mirror is attached to the guard in front of the lamp globe. These outfits are supplemented by a cataphoric galvanoscope made especially for the use of dentists, Weston milliampere-meter, etc.

H. H. Johnson, representing the Dow Portable Electric Assistant, showed some samples of that useful outfit. One was an oak case containing three cells for use where light is only required. It was fitted with one lamp, one direct reflector, one side

reflector, one tongue depressor and one mirror. Another set had an otoscope for use in the examination of the eye and ear, a cautery suitable for light cautery work, an electro magnet for the removal of iron or steel from the eye or any part of the body; a probe and sounder for finding metals embedded in the body; an electric needle for cataphoresis and electrolysis; and a head light and band for use in connection with the cystoscope and urethroscope. Another set contained a complete cataphoric outfit for dentists with light and reflector, and a perfectly regulated rheostat, which enables the operator to control the current perfectly. These outfits were highly spoken of at the convention.

Very effective use of the Lundell motor is made in the electric dental engines exhibited by John F. Hammond, 25 East 125th street, New York. These engines are very complete and show wonderful adaptability of control. The special feature of the outfit is the foot switch, by which it is possible to control both the speed and direction of the motion absolutely. The foot piece is hung on a central pivot, and the speed is regulated by steps. The regulation goes evenly in five gradations, from zero to a speed of 3,600 revolutions. Either battery or street current can be used. A new departure in this outfit is the Wappler controller, the resistance of which is a continuous coil of specially prepared carbonized wire, the regulation of which is effected by a pole running across the side, which can be easily moved backwards or forwards by the hands.

Among other exhibits was a two cell storage battery for dentists exhibited by the Ritter Dental Mfg. Co., of 563 North St. Paul street, Rochester, N. Y., which presented many points of excellence. This firm also showed an electrical dental engine for 110-volt circuits, an electrical engine for four volt battery circuit, laboratory lathes, cataphoric appliances, etc.

The electrical specialty of the Consolidated Dental Mfg. Co., of 115 West Forty-second street, New York City, was a dental hammer embodying new principles, and actuated by six cells of Partrick & Carter's dry battery. This company was represented by Dr. Barnes.

Another form of electro-magnetic dental mallet was exhibited by its manufacturers, the Russell Electric Mallet Co., of Moravia, Md., as well as a number of electro dental specialties.

An interesting collection of electro dental and surgical appliances was shown by Louis Costa, Jr., & Co., of 1225 Callowhill street, Philadelphia, Pa. The cataphoric volt selector of this firm is commended. One of the special features of this exhibit was the Cox thermopile, which is now being used to a considerable extent by dentists, and in connection with which Messrs. Costa, Jr., & Co., mentioned some promising results.

The Burnham Electric Company, 146 Franklin street, Boston, Mass., showed an improved gravity battery—the Excello—which excited much interest. This firm is receiving ample recognition in its efforts to manufacture the best possible forms of existing dental appliances, while working up a line of electrical specialties.

Other exhibitors of electrical devices were B. & E. Hanfeld representing the Waite & Bartlett Mfg. Co., of New York; the Dental Protective Supply Co., of Chicago, and the Edison Mfg. Co., of St. James Building, New York, whose fine specialties and apparatus available for dental and electro medical work have already been illustrated and described in these columns.

Steady but Sluggish.

THE course of events during the past week was sluggish, although the market was steady and conditions were such as favor a cheerful feeling. Of course it is midsummer, and there is nothing to worry the country except the war, and that seems likely to recoup us for all the anxiety and expense bestowed on it. Crops look well, and the public belief is that fall trade will be excellent. News from the Klondike goes to show that the icebergs up there will yield \$20,000,000 this season, which ought to leave some margin of profit. Now that the Cervera fleet has been snuffed out of existence, there is a brisk renewal of

Atlantic coast and West Indian shipping trade and the outlook there is most encouraging for large business.

During the week, 5,202 shares of Western Union were sold from 92 to 92½; of General Electric, 2,880 from 38½ to 39¼. In Boston American Bell Telephone sold at 275. New York Edison is selling at 131½ and Brooklyn Edison at 122½.

The copper market appears fairly active. For Lake copper 11½ cents is asked. Heavy steel rail, Eastern mill, is \$17.

Sterne vs. the Metropolitan Telephone and Telegraph Company and New York Telephone Company.

JUDGE KELLOGG in the New York Supreme Court handed down on July 18 two decisions in the suit of Simon Sterne against the New York Telephone Company, which practically leaves Mr. Sterne without any case against that company. It will be remembered that some years ago, when the Metropolitan Telephone Company reconstructed its system and made metallic circuit working the rule, Mr. Sterne refused to allow his telephone line and instruments to be changed to metallic circuit, and when the telephone company proceeded to act upon its right to terminate its contract with Mr. Sterne, the latter secured an injunction restraining the company from interrupting his telephone service, and brought suit to compel it to furnish him service at a rate to be fixed by the court. The injunction was continued pending the trial of the suit, the Metropolitan Company being authorized to change Mr. Sterne's line and instruments to metallic circuit, and he giving a bond to pay the full rate in the event of the case going against him. The case was given considerable space in the newspapers.

Some time later the Metropolitan Telephone and Telegraph Company went out of business and sold its plant to the New York Telephone Company, a concern organized to furnish telephone service in a much larger area than that served by the Metropolitan Company. Mr. Sterne subsequently secured an order to bring in the New York Telephone Company as defendant, and it was to that company's motion to vacate the order that one of Judge Kellogg's decisions referred. The decision states that this was the first opportunity the New York Telephone Company had to be heard in the matter, and that company had the right to expect that its present motion would be considered unprejudiced by any previous determination of the court had in its absence. "The order and the supplemental complaint obviously regard this defendant as a corporate body separate and distinct from the other defendant. It is not the same body under a new name or changed name. It must be regarded as having no legal relations with the other defendant or with the acts of the other defendant except those created by contract with it." The decision points out that while Mr. Sterne alleged that the New York Telephone Company assumed all "debts, contracts and liabilities" binding upon the Metropolitan Company, it is not alleged that there existed any contract with Sterne binding upon the Metropolitan Company. Even construing "liabilities" as the alleged legal liability to furnish telephone service to the plaintiff, the case is no stronger "for one cannot make more binding his burden by declaring upon paper his intention to perform what the law directs. In no way can it be reasoned that this is a contract liability. If this defendant owes any duty to the plaintiff, it is because the law imposes it." After stating that there is no precedent in support of any other contention, the opinion concludes as follows: "The law does not hold this defendant responsible for any alleged wrongful threats of the Metropolitan Telephone and Telegraph Company. That is the cause which enabled plaintiff to bring this action in a court of equity. The cause of action does not in law follow the property; the duty to furnish the service may, when a similar case arises against the new owners, it may be held to answer, but I see no ground whatever for the contention that it must answer for the threats of its predecessor in ownership. The motion to vacate is therefore granted, with costs."

The second decision of Judge Kellogg relates to a motion to vacate an order permitting the examination of the officers and books of the Metropolitan Telephone Company to procure testimony, an order in which by a supplemental complaint it was sought to bring the New York Telephone Company as successors. The motion to vacate was granted for much the same reasons as those given in the previous opinion. The original defendant had gone out of business, and no issue remained between it and the plaintiff. There was no contract between them, and the defendant, therefore, could owe the plaintiff nothing, and did not seek to recover anything. The relief sought by the action was now impossible. The decision goes on: "By the supplemental complaint the plaintiff seeks to create a living issue with the defendant, the New York Telephone Company, to obtain a substantial judgment, viz.: The judgment he originally claimed against the Metropolitan Telephone and Telegraph Company, on the ground that it has succeeded to the property and duties of the last named company. The fact that plaintiff by order of the court deemed it necessary to bring in this party as a defendant is a sufficient admission that it has a separate entity and is to be treated as a separate and distinct party; as a new party it has a right to be heard on all motions affecting the trial and especially in motions to examine books and officers to procure testimony to be used at the trial. The order here sought to be vacated as to this defendant, is a nullity. The testimony procured under this order could not be read at the trial under any issue formed with the supplemental complaint, and for that reason in my judgment, the order should be vacated. If the Court of Equity will exercise the right to fix in advance the annual rentals of telephones at the instance of an individual desiring to have his premises equipped with these mechanical facilities, it will fix such rental on a basis of reasonable profits to the company or individual directed to render such service, and this necessarily involves an inquiry into the affairs and business of that particular company or individual. The books of any other company or individual are not competent evidence on such an inquiry, they are not admissions to the party, and possess no higher grade in testimony than hearsay. For such reason the testimony sought by this order, even though the order were made on notice, could not be made available as against the New York Telephone Company. I am of the opinion that the order should be vacated, with costs, and it is so directed."

Carty's Telephone Bridging Bell.

PATENT SUSTAINED—WESTERN ELECTRIC CO. vs. MILHEIM ELEC. TELEPHONE CO.

AN important decision has just been rendered in the U. S. Circuit Court of the Western District of Pennsylvania by Judge Buffington, sustaining the bridging bell patent issued to J. J. Carty, No. 449,106, of March 31, 1891. The litigation for infringement was between the above parties, and the defence was lack of novelty and of patentability. The decision sustains the patent.

Prior to this patent it was customary to connect the call bell magnets at the several stations in series in the main line circuit together with a normally shunted call sending generator and at each station to provide a switch, which, when at rest, maintained the continuity of the main circuit through all the call bell magnets and kept the circuit of the local transmitter battery open. When, however, the switch was changed—which was done when the receiver was taken from the hook for use—it disconnected or short circuited the bell magnet or generator from the line and introduced in place thereof the telephonic transmitting and receiving instruments and closed the local battery circuit of the former. Though this switch change at the two communicating stations removed the bell magnets at such stations from the circuit, no such action took place at the other stations. Consequently the voice current had to traverse all the other magnet helices in the line and was much weakened, not only by the resistance of such magnets, but also by the counter electromotive forces or inductive resistances developed in each. These were so active and energetic as to hinder conversation, yet it was necessary that all bell magnets should be connected with the circuit, otherwise the several stations cannot signal each other. It will be noted that in this system, which is called a series-circuit, the component parts are so arranged that the current must pass through all its parts, one after another. It is so styled in contradistinction to a multiple circuit, which is one

having two or more of its parts so arranged that the current divides, portions of it passing through parallel paths afforded by the several parts. The two systems may be thus illustrated: When incandescent lights are connected in multiple circuit, the current passes to one terminal of each of the lamps which are connected to one side of a circuit and then divides up, a portion passing through each lamp to the other side of the circuit, where all these portions are reunited. Where such lamps are connected in series, all the current must flow into the terminal of the first lamp and out at the other, and so on through the successive lamps.

It also appeared impossible to obtain a perfect inductive balance in a metallic telephone circuit when the bell magnets and telephone were connected in series and such inductive disturbances manifested themselves generally in annoyances and sometimes were so intense as to prevent conversation. Now it would seem that if, instead of the series circuit connection for both call magnets and telephones, a multiple circuit or bridging connection after the manner of the simplest form of incandescent lighting was substituted these difficulties would be avoided, but the conditions were different since in a telephone circuit each station is both a generating and a utilizing one at the same time. Therefore the generating currents are likely to be short-circuited by the nearest bridge connection and thus fail to reach the more distant station which it is desired to signal. The additional fact that two diverse uses are to be made of the current at the same station, viz.: signaling and transmission of sound, and that they are to be used interchangeably between all the stations, renders necessary the addition of other means and factors to simple mere parallel arrangements. To overcome these difficulties the patentee suggested a simple and efficient remedy.

The Carty patent shows and describes a method of attaching telephone instruments in multiple between the two sides of a line, whether this line be a metallic circuit or a grounded line. The call bells are each permanently bridged between the two sides of the line and are made of high resistance and retardation. The generator at each instrument is in a separate bridge circuit which is normally open, but closed when the generator is operated. The telephonic apparatus proper is in a third bridge circuit, which, like the generator circuit, is normally open. The telephone circuit of each instrument is automatically closed when the receiver is removed from its hook for use, and this operation also closes a local circuit containing the primary of the induction coil, the local battery and the transmitter. In order that there shall not be an undue leakage of the voice currents through the permanently bridged call bell circuits, the magnets of these call bells are wound to a high resistance (usually a thousand ohms) and are also constructed in such a manner that they will have a high co-efficient of self-induction. When a generator at any one station is operated it is connected across the two sides of the line in parallel with all of the call bell magnets on the line. Part of the currents in this generator will, therefore, pass through each of the call bell magnets on the line, thus causing them all to operate if the amount of the current generated is sufficient to accomplish this result. The successful operation of this system depends on the fact that a coil possessing a high co-efficient of self-induction will transmit with comparative ease alternating or pulsating currents of low frequency, while it will form a practical barrier to similar currents having a very high frequency. The currents generated by the calling generator at any station are of sufficiently low frequency to pass with comparative ease through the call bell magnets arranged along the line, while the rapidly alternating voice currents impressed upon the line by the telephonic apparatus at any station will be compelled to pass over the main line to the receiving station without being materially weakened by leakage through the call bell magnets. At the receiving station these voice currents will pass through the telephone receiver and secondary coil of the induction coil, these being connected across the line at that station by virtue of the receiver being off its hook. This path through the receiving instrument is of comparatively low resistance and retardation and thus practically takes all of the current from the distant station.

Adopting this as a sufficient description of the device and its purpose, the court dismisses as not pertinent a number of alleged anticipations, including patents of Varley, Scribner and Van Rysselberghe.

CARD ELECTRIC CO. A receiver has been appointed for this company.

REPORTS OF COMPANIES

The Scaling Down of General Electric Capital.

A circular from President Coffin to the stockholders says: "Your directors are advised by counsel that in consequence of the impairment of its capital, the company is forbidden by the laws of New York to pay any dividend whatever until the amount of such impairment shall have been regained, or until the nominal or share capital stock shall have been reduced to the amount of the actual capital. Under existing New York law, the nominal or share capital of the company may be reduced at any time by a vote of a majority in interest of all the stockholders, and counsel advise that if any reduction be made the common and preferred shares must be reduced alike. In view of all the foregoing, your directors regard it their duty to urge the stockholders to make at once such reduction of the nominal or share capital as shall permit the payment of dividends upon both classes of stock with the least practicable delay. The consolidated balance sheet of the company of January 31, 1898 (being the close of the last fiscal year), appears in the last annual report of the company. Your directors, being of the opinion that the valuation at which patents, franchises and good will were carried in this balance sheet—namely, \$8,000,000—was excessive, and that the fair and reasonable value of this item is the sum of \$4,000,000, have by resolution directed this item to be reduced to that amount upon the books of the company, as of June 30, 1898. Taking into account the estimated earnings of the company to August 10, 1898, your directors believe that a reduction of the share capital of the company as of August 10, 1898, to sixty per cent. of its present amount would make the share capital of the company substantially equal to the amount of the net assets which will then be on hand over and above the debts and liabilities of the company. Any surplus net earnings from and after that date will then be applicable to the payment of accrued dividends on the preferred stock and future dividends on both classes of stock."

THE UNION TRACTION CO. of Philadelphia has converted the deficit of \$851,900 in 1897 into a surplus of \$24,600, showing a gain for the year of \$876,500 under the management of Mr. Parsons.

TRADE NOTES AND NOVELTIES

Affairs of the Western Telephone Construction Co.

The Western Telephone Construction Company, of Chicago, is at present operating its factory night and day, employing something over two hundred hands. Since the reorganization of the company, its business has been largely increased. The shipments for the current month promise to be the largest in its history. During a period of forty-five days, dating from the 1st inst., thirty-two complete telephone exchange equipments will be shipped from its factory, including the central office equipment of over 2,000 stations capacity for the Newark Telephone Company, of Newark, N. J. This represents the most extraordinary output in the history of independent telephone manufacture.

Following the reorganization of this company, some differences arose between the stockholders, and thus certain persons have circulated reports of trouble in the Western Company, some going even so far as to make the statement that a receiver had been appointed.

The facts are that the company's officers are in entire harmony, and its financial and business condition is far more substantial than at any time in the past, while its responsibility and reli-

bility have considerably increased of late. The present volume of business with which it is favored, calling for overtime work in the manufacturing department, although the company has recently increased its manufacturing capacity, will certainly tend to create confidence in the present and prospective prosperity of the concern. Its officers positively state that its financial resources, as shown by its balance sheets, much exceed in net value the total amount of its capital stock under its present capitalization, and the success of the company should be a matter of congratulation on the part of the independent telephone users of this country whose interests it has so vigorously and conscientiously promoted.

Multiphase Cable and Lower Fire Insurance Rates.

AS already reported, the Suburban Underwriters' Association, on June 28, increased the rebate allowed for the Auxiliary Fire Alarm System to 10 per cent., when the boxes are connected by "multiphase" wire, so that the system becomes automatic, as well as manual.

The value of automatic connection with public fire alarms has been for many years, says "The Insurance Press," universally recognized by the underwriters, and encouraged by liberal rebate allowances. Thus far the only systems of public automatic alarms connecting with public fire departments are operated through their own central stations, as fire departments do not allow the thermostats in general use to be connected with the street boxes. The expense of wiring and the cost of central office maintenance are so great that the thermostatic alarm business cannot be made profitable outside of the very large cities, and even in them is never extended into the outlying districts, where protection of this kind is greatly needed. The value of thermostatic alarms, as shown by experience of many years with the central office system, proves the immense importance as a factor in reducing fire losses of a practicable system of automatic alarms which can be operated outside of the comparatively narrow limits of the central office thermostatic system. This extension has now become not only possible, but practicable, and is to be at once brought into use. The auxiliary system, as already well known, has for years rendered service of very great value, by providing means for operating street boxes from the interiors of buildings. In every one of the cities where the auxiliary alarm is used it has saved many times the rebates which have been allowed by the underwriters.

Still, manifestly, its usefulness would be greatly enhanced if alarms could be sent in from an auxiliary equipment, at a time when the premises are unoccupied and unwatched. It has never been a matter of any mechanical or electrical difficulty to connect ordinary thermostats so as to operate in the same circuit with the auxiliary boxes, but the danger of unnecessary alarms has prohibited this. The recent invention of the "multiphase" cable has been adapted for use in connection with the auxiliary system, so that this becomes also automatic without the sacrifice of any of the peculiar features of safety from false alarms, which is the foundation of the willingness of fire department officials to allow its connection with street boxes. The combined system also is like the auxiliary system itself, always under automatic test, so that any disarrangement of the wires or batteries is instantly made known. When an auxiliary equipment is installed with the multiphase wire the auxiliary boxes located on each floor will be connected by these wires, which will be run through every room in the places where it would seem most likely for a fire to occur, and especially into dry rooms, storage rooms for inflammable materials, and generally through whatever may be regarded as the danger points in each case.

Whenever the smallest flame reaches any inch of this wire the alarm is instantly transmitted to headquarters as if the street alarm box had been operated by hand. Every foot of this "multiphase" wire when thus installed becomes an ever-vigilant watchman, ready when needed to instantly transmit a fire alarm to department headquarters. Through this combination of the auxiliary system and the multiphase cable a new and most important advance in fire alarm telegraphy has been made. It is now possible to make an incipient fire send in its own alarm to fire headquarters in every city or town in the United States which has a public fire alarm telegraph. The managers of the auxiliary automatic alarms do not intend to come into competi-

tion with the established thermostatic central offices, but in furnishing automatic alarm facilities in the vastly larger territory in which the central office systems, for reasons stated, have never operated, they will inaugurate a new era of improvement in fire alarm telegraph facilities which will doubtless be as readily welcomed by all underwriters as it has been by the Suburban Association.

The Burton Electric Welding, Forging and Brazing Machine.

AFTER years of experimenting with numerous welding devices and machines for electrically forging and brazing metals, the Burton Electric Smelting Co., of Boston, Mass., have succeeded in producing an outfit which is claimed to meet all the requirements of modern practice. The complete installation which is shown in Fig. 1 is composed of the generating ap-

FIG. 1.—BURTON ELECTRIC SMELTING CO.'S DIRECT TRANSVERSE CURRENT WELDING, FORGING AND BRAZING MACHINE.

paratus, the controlling devices, the transmission parts, the anvil electrodes and means for applying the mechanical pressure and current. The machine makes a lap weld without injury to the metal, and it is well known that a lap weld is superior to a butt weld. The operation is performed on the anvil in view of the workman. The piece to be heated or welded rests on the electrode block connected with the anvil. By depressing the foot lever the revolving electrode is brought into contact with the metal and the heating effect takes place. As soon as the re-

ELECTRODES FOR BURTON ELECTRIC WELDING, FORGING AND BRAZING MACHINE, AND ATTACHMENTS FOR SPECIAL WORK.

quired heat is obtained the foot lever is released and the weld completed by hammer blows on the anvil.

In Figs. 2 to 13 inclusive are shown various types of electrodes for different kinds of work in connection with the Burton Electric Smelting Company's direct transverse current welding, forging and brazing machine.

ADAMS-BAGNALL ELECTRIC CO., of Grand Rapids, Mich., has been incorporated with a capital stock of \$225,000.

The Hubbard-Mortson Automatic Time Switch for Turning off and on Electric Currents.

FROM time to time several cumbersome and more or less clumsy appliances for automatically turning off electric currents have been put upon the market. These have accomplished the one purpose of turning off the switch and a simple alarm clock movement has usually released a gravity contrivance whereby the cutout is accomplished. The automatic time switch clock illustrated herewith is claimed to be the first appliance that has ever accomplished the twofold movement of turning on and off the electric switch at any time of the day or night at which the clock may be set. This is without doubt one of the most important mechanical appliances for controlling electric circuits, and will be of interest to the electrician, engineer and every householder.

As may be seen from the illustration, the automatic time switch clock presents a handsome appearance. It looks like an elegant French clock with its polished movements, brass corner pillars and panels of plate glass enclosing the clock movement and switch train. The case is mounted upon a substantial base of slate upon which is placed an ordinary four-pole electric switch. The wires to be controlled are cut into this switch in the ordinary manner.

The operation of the time switch is exceedingly simple, but most practically and thoroughly effective. A twenty-four-hour dial, which makes one revolution every day, revolves under a fixed pointer at the top. At the back of this dial are supplied two movable pointers held in position, with sufficient friction, by a spring disc. These pointers may be set at any time of the night or day, and are fixed rigidly in position, when set, by pins which engage in a row of holes parallel with the circumference

HUBBARD & MORTSON AUTOMATIC TIME SWITCH FOR ELECTRIC CURRENTS.

of the disc. When the first pointer reaches the reading point at the top the other end trips an alarm wire which connects with the time hook and sets in motion the train which turns the switch. As time passes, the second pointer approaches the point of reading, reaches it and sets the train in motion again, accomplishing the second motion of the switch, and turning off the lights. Absolutely all the attention that this requires, after having been set for the hours desired, is winding once a week.

The time switch is used most practically and thoroughly for the controlling of electric lights in show windows, burglar alarms, arc light circuits, and, in fact, everywhere where electricity is used. Different sizes of switches are put into the clock in accordance with the strength of the current it is required to handle. The mechanism is well made and the clock train thoroughly reliable, having been manufactured under the personal supervision of Frank E. Hubbard, the well-known horological expert. The new time switch is meeting with the most hearty welcome from all electricians for its practical utility, its money saving qualities, and its great convenience. The switch arranged on a slate base meets all the requirements of the National Board of Underwriters. The Hubbard & Mortson factory, where the new time switch is made, is located at 42 Union place, Hartford, Conn.

Advance of the Storey Motor.

The Storey Motor & Tool Co. have moved their main office and factory from Philadelphia to 464 South Broad street, Trenton, N. J., in the plant with the Trenton Iron Co. This change is made necessary by the greatly increased demands for the electrical machinery of their manufacture, particularly their multipolar, entirely enclosed, dust and moisture-proof motors, the first of this style to be placed on the market, several years ago.

The motors at present manufactured by them have been improved both mechanically and electrically, all advantages having been taken from years of past experience, the machines being second to none and having some features possessed by no others, together with light weight, high efficiency, slow speeds and special form which makes them particularly adapted to all classes of direct connected, machine tool, hoist, crane, mill, mine, and, in fact, any variety of combination.

With their increased facilities the company will also put on the market their open type machines for all classes of standard work, together with several lines of specialties which up to the present time they have been unable to push. Within a short time the company expects to have everything running in proper order, and will be pleased to hear from any of its old customers or give any details and descriptive matter regarding its machines to any parties wishing information.

Safety Conduit Company, Pittsburg—The "Loricated."

THE advent on the market of the products of this firm, which are known as "Loricated" electric conduits, marks a decided step in advance in the line of safety appliances for the protection of interior electric wiring. The conduit proper consists of ordinary steel tubing like gas pipe, made in ten-foot sections, threaded at both ends, and provided with suitable couplings, but which has undergone a sort of japanning process, by means of which the tubing has received a tough, smooth "Loricated" covering, both outside and in, and which is so constituted that it will not crack in bending, while it resists perfectly the action of moisture, of acids and alkalis. The interior is left smooth as glass, which facilitates the insertion or extraction of the wires, without the use of soapstone or any

THE "LORICATED" SAFETY CONDUIT.

other lubricant. T's, elbows and curved angles are also provided, but are not always necessary, owing to the facility with which the tubing can be bent. When in place, it furnishes a safe armor for the wire, so that it cannot be injured by nails or receive any mechanical injury, while they are entirely protected from any accumulation of moisture. These conduits are also especially adapted for the protection of wires in mines and in mills where there is an excess of moisture, like paper mills, or buildings devoted to chemical processes where the vapors contain injurious acids. The products of the company have been tested and approved by the experts of the National Board of Fire Underwriters and by many local boards, and wherever installed they have given satisfaction both to inspectors and to workmen, who are said to like them on account of the ease with which they are installed, and because by reason of being able to bend the tube around corners, a much better job can usually be made than where elbows are employed. This feature also renders the cost of labor in installing comparatively low.

The company not only manufacture piping for interior construction, but also "Loricated" soil and vent pipes. This product consists of the ordinary castiron sewer pipe, which has been treated in the manner described above. This prevents the action of electrolysis, and gives a smooth interior surface which facilitates the passage of the sediment to the sewer outlet. It results in lasting qualities equal to those of terra cotta pipe, and more healthful from a sanitary point of view, because the joints can

be lead caulked and thus prevent the possible escape of foul gases.

Another use to which "Loricated" pipe is put is for water service pipes, and especially in places where sulphur and acids abound, the coating on the pipe being found to resist the effects of all sulphurous acids, alkalis, etc. It might also be mentioned that any ordinary engineer or pipe fitter can install such pipe, for the reason that what is used for this particular purpose is ordinary gas pipe of standard dimensions, thread, etc. In the process of manufacture all rust, scale and other obstacles are removed from the tubing, after which the "loricating" compound is applied. The process is the result of eighteen years of experimenting by the superintendent of the works, and is exclusively owned by this company.

The works are located at Rankin Station, about eight miles from Pittsburg, on the line of the Baltimore & Ohio, and Pittsburg & Lake Erie Railways, both of which provide free switching facilities for the delivery and shipment of material. The tubing is purchased in carload lots from the neighboring pipe mills, and a large stock is always kept on hand.

The works consist of a number of substantial brick buildings, with a two story isolated building for office purposes. The equipment is ample for promptly turning out large orders, one of the largest of which, that was recently supplied, being for 150,000 feet for the new Washington post-office. Other large recent orders include the full equipment of the new Studebaker Building in Chicago, and the Prudential Building at Atlanta, Ga.

Orders for Sterling Telephone Apparatus.

The possibility of securing central office equipment similar to that used by the Bell companies seems to have an allurements for the independent telephone companies. They believe that what is good enough for, and has been perfected in the Bell Company's use, by way of apparatus, is surely good enough for them. Acting upon this belief, the following companies have placed orders with the Sterling Electric Company, of Chicago, as follows: The Mutual Telephone Company, of Des Moines, Iowa, 2,000 drop standard metallic circuit board; Lafayette Harrison Telephone Company, Lafayette, Ind., the equipment complete for a 1,000 drop exchange. This consists of switch-

boards, cable terminals and protectors and distributing boards. The Plymouth Telephone Company, of Plymouth, Ind., 200 drops metallic circuit board; the Schanche & Fair Electric Company, of Chrisman, Ill., 100 drops of standard metallic circuit board. This apparatus when installed will it is claimed give the independent companies the same central office equipment as the Bell Company are using.

Westinghouse Air-Brake Prosperity.

Mr. George Westinghouse, Jr., takes highest rank among the princes of invention and finance. At the recent meeting of the stockholders of the Westinghouse Air-Brake Co. it was decided to increase the capital stock from \$5,000,000 to \$11,000,000 by distributing 100,000 shares at a par of \$5,000,000, to stockholders as a stock dividend, and to hold the remaining 20,000 shares of a par of \$1,000,000 in the treasury for the purchase of property. During the last fiscal year the company has paid its stockholders four regular and four special dividends amounting to 50 per cent. cash, and the present dividend of 100 per cent. makes the earnings and distribution unprecedented in the history of Pittsburg concerns. The net earnings of the company in ten years have been \$17,500,000, while the cash dividends have amounted to \$14,596,000.

COLUMBUS, O. The City Council has voted down, after investigation, a scheme to install a municipal telephone plant.

Mr. Paul Hoenack.

For twenty years and more, Mr. Paul Hoenack, of 191 Worth street, has been prominently identified with the development of electrical devices of all kinds. In that period, he has exercised his skill as a mechanic in every branch of the science and has worked for almost every electrician of note in this country and for many abroad. Apparatus made by him is to be found in telegraph and telephone centres, in submarine cable stations all over the world, in colleges and private laboratories, in the army and navy, in electric light and power stations. Indeed, the name of "Hoenack" can be seen stamped on instruments of many kinds wherever the pulse of civilization throbs through an electric circuit. It gives us great pleasure to be able to utter these words of well deserved commendation for one who has done so much for the profession and whose talents and skill have contributed no little to making practical many important inventions which are benefiting mankind at the present day, and some of which, perhaps, would never have been perfected without his assistance.

To all inventors struggling with difficult mechanical problems, or disheartened by incomplete or imperfect instruments, we heartily recommend Mr. Hoenack as competent to achieve for them whatever the highest mechanical skill and long varied experience can accomplish. Mr. Hoenack's factory and office are located at 191 and 193 Worth street, New York.

The Holtzer-Cabot Gas Engine Igniter.

ONE of the most satisfactory machines devised for igniting gas and gasoline engines has recently been placed on the market by the Holtzer-Cabot Electric Co., Brookline, Mass. The machine, illustrated herewith, is constructed with a permanent magnet field and an armature of the drum type, similar to that used in our direct current motors. It has self-feeding carbon brushes and is self-lubricating, being provided with grease cups. It is dirt, oil and moisture-proof. It can be run in either direction, and may be driven, if the fly-wheel of an engine

HOLTZER-CABOT GAS ENGINE IGNITER.

runs true, from a friction pulley bearing upon same, or may be belted to fly-wheel or any convenient shafting. The speed should be about 2,000, but it can be run at any speed, say 1,500 and 2,000 r. p. m. The battery, which may be 4 or 5 cells of any ordinary open circuit form, is used but for a few moments to start the engine, consequently will last indefinitely. The advantage of the dynamo over batteries for lighting gas in gasoline engines is apparent. It is well known that the strength of a battery current on this class of work rapidly gives out, the battery soon becomes exhausted, requiring frequent renewals of solution and zincs. Besides this, trouble often arises through the battery connections becoming corroded and opening the circuit. The dynamo, on the other hand, can be depended upon to give a constant current.

TELEPHONING from Manchester to Brussels, via London and Calais, has been tried with great success.

**Patterson, Gottfried & Hunter, Ltd.**

The above well-known dealers in machinery, metals, hardware, tools and supplies, located at 146-150 Centre street, New York, have just issued a very complete catalogue, illustrating the numerous machines sold by that company. The Springfield-Muller engine lathes are described in detail, and their numerous advantages pointed out. There are further shown Springfield crank shapers, power presses, centering machines, hand milling machines, water tool grinders and a great variety of chucks, arbors, grinding and polishing machines, and patent counter-shafts. The catalogue will be sent to any one on application.

Chloride Accumulators.

The Electric Storage Battery Co., of Philadelphia, Pa., are sending out circular No. 42, which contains a description of the installation of chloride accumulators in the plant of the Claremont Electric Light Co., of Claremont, N. H. This plant is one of the most unique of its kind in this country and is exceptionally interesting, because it conclusively exemplifies the advantage of the application of storage batteries to small lighting installations. The pamphlet contains a complete description of the plant, and shows illustrations of the storage battery room, switchboard, switchboard connections and a view of the dam and power house.

Farr Telephone and Construction Co.

A very complete catalogue of telephones and telephone supplies has recently been issued by the above company. It is called "Catalogue No. 5," and is a handy book of information as well as a trade catalogue. Besides enumerating the numerous telephone articles manufactured and sold by the company, the book contains a complete list of electrical supplies of every description, such as motors, lamps, alarm clocks, phonographs, graphophones, telegraph instruments, medical batteries, etc. It also contains numerous valuable diagrams of connections, wire tables, electrical data, list of books and a complete index. This company is located at 337 Dearborn street, Chicago, Ill.

"Some Facts about Batteries."

This is the name of a little pamphlet sent out by Wm. Roche, maker of "New Standard" dry batteries, located at 259 Greenwich street, New York. He calls attention to the fact that he has made over 1,250,000 cells that have been sold under the names of "Exeter" and "Mesco," and which were made from a formula known only to him. The "New Standard" is claimed to possess great strength, life, quick recuperation and economy superior to all. It is a good battery for telephone work and is well adapted for electro-medical apparatus, dental surgery, gas lighting, railroad signals, etc. The price of the battery is low while the quality is high, and its voltage is from 1.55 to 1.60, and its amperage from 7 to 12. The "New Standard" batteries are made in numerous sizes, one of them, called the No. 2, measuring $3\frac{3}{4} \times 1\frac{7}{8}$ inches, this being the smallest practical battery made. Physicians have recognized the merits of this battery for portable apparatus.

ADVERTISERS HINTS

THE STERLING ARC LAMP CO., 214-222 West Twenty-sixth street, New York, have something to say about several styles of their enclosed arcs.

THE WESTERN ELECTRIC CO., Chicago and New York, advertise the Weston station ammeter in sizes up to 30,000 amperes capacity. They are headquarters for electrical testing, measuring and station instruments.

THE ELECTRICAL EXCHANGE, 166-174 South Clinton street, Chicago, present a revised list of electrical machinery

and supplies which they have on hand, ready for immediate shipment.

THE WALKER COMPANY, Cleveland, Ohio, illustrate an isolated plant of 90 k. w. capacity.

THE ELECTRIC STORAGE BATTERY CO., Philadelphia, Pa., publish a letter from a company using a battery as a means of trolley regulation. It is so assuring in its tone as to leave no doubt of the very satisfactory results obtained.

J. JONES & SON, 62 Cortlandt street, New York, advertise toggle bolts.

NEW YORK NOTES

JOHN A. ROEBLING'S SONS CO. have recently finished a large order for trolley wire, etc., to be used in connecting Odawara and Yokohama, a distance of about forty miles.

J. JONES & SON, 62 Cortlandt street, New York, have taken an export order for their make of switchboards, switches, panel boards, electric light fixtures and sundry specialties. It is a large shipment, intended for the inside equipment of a large electric light plant, and will keep their factory busy for the next six weeks.

INDUSTRIAL RAILWAYS. Under this heading the C. W. Hunt Company, of 45 Broadway, New York, issue a book giving full information on the many perplexing questions which arise in the minds of those contemplating the installation of such tramways. All questions as to best gauge, radius of curves, weight of rail, switches, style of cars, etc., are fully met and answered. Central station managers who have to handle coal and ashes, will find in this book a most valuable guide. The C. W. Hunt Company also make a large variety of coal handling machinery, electric and steam hoisting engines, conveyors, etc.

OSTERBERG & SUTTON, consulting engineers, 11 Broadway, report that they are about to remove to larger quarters in the Bowling Green Building. This is the fourth time in a year and a half that this young firm's business has outgrown its floor space. Among the work which has come to their office during the last few weeks are, besides considerable expert work in the nature of tests, the appointment as consulting electrical engineers for the Trinity Corporation; Patchogue Manufacturing Company, where, by the way, for the first time, large curtain looms are being equipped with direct connected motors; shirt factory of M. Price, in Paterson, N. J.; the Aguilar Public Library, some improvements in the stores of Simpson, Crawford & Simpson, and a number of minor matters.

THE MICA INSULATOR COMPANY, of New York and Chicago, report a gratifying demand for their "Micanite" segments for electric light and power generators. Some heavy orders are being executed at the factory in Schenectady, N. Y. Many of the large generators now under construction have for their commutator insulation "Micanite." The heavy increase of the company's business during the last few months is largely due to the improved process of manufacturing a perfect commutator segment. They offer to send free to any machinery builder or electrical repair concern a set for any one of the smaller machines, free of expense. Parties interested in the economical insulation of electrical machinery will do well to write the company at their office, either in New York or Chicago.

SYRACUSE, N. Y. The Syracuse Construction Company are erecting new buildings in connection with their electric railroad plant. The buildings consist of a boiler house 60x90 feet, which is an all fireproof building, having steel framework covered with corrugated iron on the sides and roof. There is also an engine room 65 feet wide by 80 feet long, having a steel frame and brick sides. The other building is a car barn and repair shop, 65 feet wide and 170 feet long. This building also has steel framework construction, with corrugated iron sides. All these buildings have been designed and are being erected by the Berlin Iron Bridge Company, of East Berlin, Conn.

JOHN THOMSON PRESS CO., 253 Broadway, New York, are issuing some exceedingly handsome blotters, printed on one of their Colt presses, such as was shown at the Electrical Exhibition. The blotter has the American and English flags embossed in colors back of a United States shield which is sup-

ported by the eagle, lion and unicorn in gold, with this legend: "America-Britannia; one root, two branches; one language, two flags." The sentiment is good enough for us; the blotter is good enough for any one.

WESTERN NOTES

DETROIT MICH. The Detroit Switchboard and Telephone Construction Co., Majestic Building, are branching out and are now making up the preliminary estimates on work for the entire construction of independent exchange plants at New Orleans, La., and Evansville, Ind. The growth of the Company is an indication of the large amount of work being done in the construction and maintenance of independent exchanges throughout the West and South.

CENTRAL ELECTRIC CO., of Chicago, report a brisk trade on lightning arresters, and are issuing some very attractive circulars on the Wurts arrester, also the Garton arrester.

ELECTRIC APPLIANCE CO. are very proud of the fact that they will soon complete the seventh year of their electrical supply business. The Electric Appliance Co. claim, and we believe justly, that after confining themselves strictly to the electrical supply business as they have for this period of time, they should be in the best possible position to handle that branch of the electrical business successfully. It is very apparent from the volume of business they are now doing and their position in the electrical field that their business has been thus far very successfully handled.

No. 535.

Means For Detecting the Presence of a Ship or Iceberg.

BY HERMANN HERBERTS.

THE recent Bourgoigne disaster connected with such heavy loss of life, such fearful dramatic scenes, where egotism was predominating to such extent, that beastly barbarous means were resorted to in butchering and annihilating the weaker

FIG. 1.—THERMOPILE AND ITS CONNECTIONS.—HERBERTS' APPARATUS FOR DETECTING THE APPROACH OF OBJECTS AT SEA.

element, has caused a deep and everlasting impression upon its survivors, upon everybody endowed with a fellow-feeling.

The average person lacks coolness of mind in such critical moments, and losing all self-control shake that of those so far unaffected. It seems to me that travelers should be made familiar with the safety appliances on board, and I venture to express the hope that the Bourgoigne disaster will not only cause the different navigation companies to give to their patrons practical lessons in using and applying such expedients, but also such further information as may be of benefit to them in case of accidents. As to the matter of life-boats, improvements seem highly desirable and particularly to quick and efficient means for launching them. Many lives were lost just on account of this deficiency. It should be made compulsory for each vessel to have a total carrying capacity of their life-boats, exceeding by 10 or 20 per cent. the maximum number of passengers carried. This Bourgoigne disaster has stimulated within me the desire of finding some such suitable means whereby collisions at sea may be avoided.

Before entering into a discussion of these it may be in order to mention a few methods of signalling, now in use.

In a dense fog, of course auricular signals must be resorted to, and among these we have with an approximate hearing distance in miles the following:

The air siren.....	10 to 12 miles.
The steam siren.....	8 to 10 "
The trumpet	6 "
The bell	1 mile.

For receiving the sounds the eophone, topophone or similar instruments have been employed with more or less success. The object of these instruments is to furnish a means whereby to determine the direction from which the sound proceeds. Under existing conditions it is necessary that both vessels be active, not only in giving signals, but also in "attempting" to intercept them. The safety of a vessel, therefore, not only rests with its own crew, but largely depends upon the watchfulness of the other vessels.

A good deal of blind confidence is therefore placed in any stranger who may come along; it is not this alone which makes navigation dangerous during a heavy fog, it is made much more so on account of atmospheric conditions which, as yet, are not fully understood. At times, it is impossible to perceive the phonorous signals when the steamer is near by, while the signal was plainly heard from some larger distance. As to the cause of this surprising interruption (seeming) in the propagation of sounds, investigations have been carried on by the United States, Germany and France. The investigations made by Major Livermore in compliance with the U. S. Admiralty have thrown some light upon this subject. It has been deduced that obstructions to sound or an irregular formation

FIG. 2.—HERBERTS' ELECTRICAL METHOD FOR DETECTING THE APPROACH OF OBJECTS AT SEA.

of the coast not only affect the strength but also the propagation of the same. Obstructions behind the source of sound will reinforce them in a similar manner as a screen will reflect the light. Rain and snow will have a great influence upon the direction of the sound.

At the first thought it seems that wireless telegraphy would meet all requirements for signalling. Reflecting upon this will soon convince us that each and every vessel afloat must be

equipped with a complete set of apparatus. Even if their use were made compulsory—then again would the safety of a vessel largely be dependent upon the other vessels in a similar manner as outlined above. Although the introduction of this kind of apparatus would make navigation safer, the location and movements of other vessels could nevertheless not be determined. Besides these, there are icebergs and floating wrecks.

Taking all in all, it is desirable to find a means which will indicate the nearness or approach of any object.

It is well known that any object, when its temperature is higher or lower than that of the atmosphere surrounding the same, will either send forth heat radiations, or else, in the other case, absorb heat from its surrounding medium.

If we can construct an apparatus which is acted upon by such heat radiations, and if the apparatus be so sensitive that it will indicate the radiations, even if they be exceedingly weak, then we have a means which may be advantageously employed in navigation. As soon as we can intercept the radiations sent forth from a vessel we need not depend upon our ear or eye to locate the same. A modification of the thermopile or the radiophone may be employed in connection with this problem.

Fig. 1 shows part of an apparatus as proposed by me to the end of detecting the approach or nearness of any vessel, iceberg or obstruction. The two thermopiles T and T_1 are surrounded by an insulating casing C and are attached to a shaft S which may be revolved slowly. The insulated rings R_1, R_2, R_3 serve to establish a permanent connection of the thermopiles with the brushes B_1, B_2, B_3 , whence wires may be led to the pilot house to the observation or indicating apparatus. The thermopiles are enclosed in a suitable compartment such as to exclude all air currents and to afford protection from the radiations of the sun and the vessel itself. For this reason the whole is mounted on the outer side of the vessel. A flat $\cap$ shaped double walled casing (not shown) surrounds the compartment C_1 ; the outer chamber of the former is filled with alum solution for the purpose of intercepting radiations due to the rays of the sun, either striking directly or being reflected from the water and also for intercepting those which are emitted from the vessel itself. The inner chamber may be attached to a continuous water supply so as to remove all heat which the alum cell may have absorbed and also to maintain the chamber C_1 at a constant temperature.

Fig. 2 shows a diagram of connections. A junction of two of the free ends of the thermopiles T and T_1 is led to the middle ring and thence over the brushes to the two galvanometers G_1, G_2 , here shown of the D'Arsonval type. The other terminals of the galvanometer coils C_1, C_2 , connect through adjustable resistances $X R_1, X R_2$, and switches S_1, S_2 , to their respective outside rings R_1 and R_2 .

For observation a galvanometer scale may be employed or perhaps an automatic indicating device as shown in Fig. 2. A light aluminum arm A , fastened to the movable galvanometer coil swings between two adjustable contacts D_1, D_2, D_3 and D_4 . A local circuit including batteries E and bells is completed should this arm be turned through a small angle. For indicating the exact position of the thermopile a large number of contrivances may be constructed. In these it should be aimed at to have a position indicator P operated by the same current as that which revolves the thermopiles.

Suppose now that in foggy weather, when we cannot see, when we are in fear of being deceived by the sound, we start this apparatus and make ourselves independent of the watchfulness of other vessels.

A vessel approaches—we are not aware of it—the radiations given out by the ship are too weak to affect the apparatus—we come nearer each other—a stronger current is set up in one of the thermopiles at the moment it points in the direction whence the radiations proceed. Instantaneously the galvanometer coil is slightly turned, the aluminum arm makes contact and causes one of the bells to give a short ring. This happens once at every half revolution as then the second thermopile becomes active. As the distance between the vessels diminishes, the effect will naturally increase and a contact is made covering a longer period of time. Watching the instantaneous position of the revolving position indicator P at the moment the bell rings and simultaneously cutting out one of the thermopiles by switch S_1 or S_2 , will immediately give us an approximate knowledge of the direction from which the vessel is approaching. To obtain a more accurate knowledge the adjustable re-

sistance may now be manipulated. It being in circuit with the galvanometer the current from the thermopile will, of course, be cut down. Under normal conditions, i. e., with the resistance cut out, the bell will operate for a certain length of time, depending upon the amount of radiations sent forth from the nearing vessel as well as the time of exposure of the thermopile to their influence; this again depends upon the speed of the revolving thermopiles. The purpose of the resistance then is to cut down the action of the thermopile to such extent that the aluminum arm makes contact only at the instant the maximum current is being produced. As this can occur only when the thermopile points directly toward the strange vessel, its position is immediately ascertained by simply moving the contact lever until the bell gives the shortest obtainable ring. For all ordinary purposes the observation of the slowly moving position indicator arm P will therefore be sufficient. A small adjustable pointer P_1 , which may be swung around the outside casing of the position indicator P , may serve to fix this position.

By the increased or diminished action of the thermopiles we know whether a vessel approaches or whether it recedes; by watching the position indicator we know whether the vessel is moving toward the right or toward the left. These means therefore enable us not only to ascertain the presence of a vessel, but also to follow its movements and all this is accomplished by simply adjusting the rheostat, listening to the bell and watching the position indicator.

Safely passing the vessel, we now come near an iceberg. The effect is similar as before; the current produced in the thermopile is, however, now flowing in the opposite direction, causing the coil to turn the opposite way and also a different bell to give its warning signal.

It is possible therefore to tell the nature of the obstruction, whether it be a vessel or an iceberg. In the case of a floating wreck, more difficulty is to be expected as its temperature will not differ very much from that of the surrounding atmosphere. It may however be, that if its entire exposed surface is in moist condition a sufficient fall of temperature is produced to affect the apparatus and to do likewise on account of radiations given out due to exposure to the rays of the sun. For the same reasons it may also be possible to tell when nearing a coast.

The double thermopile is proposed for the purpose of increasing the action of the apparatus as then it can be revolved at a slower speed, in that way giving a longer exposure to the radiations—while at the same time the vessel is better protected. A combination of four of these would undoubtedly improve the effects considerably as the speed may then be cut down still lower. A plurality of thermopiles suitably arranged would not require to be revolved. Of course, each side of the vessel should be provided with a complete apparatus.

The indicating apparatus, i. e., the galvanometer should preferably be mounted so as to be free from vibration and in a similar manner as that employed with the compass, to make it independent of the ship's motion.

Now, a few remarks touching upon the radiophone. Berzelius, in 1817, discovered selenium, while Knox, in 1837, found that it was an electrical conductor. May discovered that its conductivity is much influenced by light. In their experiments physicists used the galvanometer, while Bell used the telephone. Bell and Tainter subsequently constructed the photophone, its receiver consisting of metal discs insulated from each other and covered with selenium. A ray of light reflected from a mirror diaphragm which is spoken against, after passing through suitable concentrating lenses is reflected to a distant parabolic concave mirror and thence focussed upon a selenium cell, which has a telephone receiver and battery in its circuit. Sound was in this manner transmitted over a beam of light. Later experiments showed that sound can be transmitted more efficiently by non-luminous heat rays. Mercadier then constructed the radiophone. In this instrument soot or lamp-black is made use of, forming a bridge between the two electrodes which are in circuit with battery and telephone. In some experiments Graham Bell used a bottle or test tube, covered or filled with soot. Throwing the focussed light on these would produce a sound if the rays be of intermittent nature.

It is a fact then, that heat rays will affect the conductivity of such radiophonic apparatus. Whether their application to the above end could be accomplished, seems at this moment difficult to answer. If its sensitiveness can be brought up to that

of the thermopile, and if no serious mechanical difficulties be met in maintaining the soot in the proper place, then it would become a simple matter to apply the radiophone also for the purpose stated.

My conception of applying these means dates back to July 7, 1898. I will not commit myself in stating that such methods as outlined above are absolutely feasible under all conditions; nevertheless, they appear worthy of a careful perusal and study. Certainly a large number of factors must be dealt with in the attempt of solving this problem so fascinating and interesting, such as for instance the effects of warm winds, the Gulf stream and others.

Seeing all the possibilities, I most heartily advance these rather incomplete ideas and hope that the press here as well as abroad will contribute its share in discussing the subject. I also express the hope that all those interested will not withhold their ideas and further, that influential parties will lend their aid to bring about a realization of this problem.

A Capillary Electrometer for Electrical Measurements.¹

BY CHARLES FREDERICK BURGESS.

MANY of the measurements made in practical engineering work require the use of a sensitive electrical instrument, and owing to the demand for such an instrument the galvanometer has reached a high degree of perfection in some of the latest and improved forms. There is still much to be desired, however, in the way of portability, rapidity of reading, simplicity, cost and freedom from the effects of external influences such as mechanical vibration and varying magnetic field.

It is my purpose to call attention to the applicability of the capillary electrometer for practical electrical measurements, as a means of overcoming some of these defects. Although the principle upon which this instrument works was discovered about twenty years ago, its use has hardly extended beyond a very limited application in scientific research, and from some of the excellent properties which it holds as a measuring instrument this seems to be a surprising fact.

This principle is the change of surface tension of two liquids

FIG. 1.—BURGESS CAPILLARY ELECTROMETER.

which are in contact (preferably mercury and dilute sulphuric acid) in a capillary tube, and the meniscus which is formed at the separate surface moves, upon the application of a potential difference to the two liquids in question. It is the movement of this meniscus which corresponds to the movement of the galvanometer needle in using it as a measuring instrument.

The only reason for the comparatively limited use to which the capillary electrometer has been put appear to be that it has not been made into a portable form, as glass and two liquids

enter into its construction, and that great care is necessary to keep it in good condition. The form of instrument herein described was designed with the view of overcoming these objections. Fig. 1 illustrates the construction, τ being a rather thick glass tube having a platinum wire sealed in the lower end. A layer of mercury covers the platinum wire, and the tube is nearly filled with the electrolyte κ , which consists preferably of a dilute solution of sulphuric acid. A capillary tube c , made by drawing out a piece of thermometer tubing, rests against the side of the glass and is held firmly in place by a tightly fitting rubber stopper inserted in the top of the large glass tube, enclosing an air space Λ above the electrolyte. A piece of flexible rubber tubing is fitted on the upper end of the capillary and

FIG. 2.—MEASUREMENT OF INSULATION RESISTANCE WITH BURGESS CAPILLARY ELECTROMETER.

wrapped tightly to prevent leakage. This tube, being filled with pure mercury, is closed by a piece of glass into which platinum wire is sealed and again wrapped tightly with copper wire. On compressing the pinch-cock P , mercury is forced through the capillary and upon slightly releasing the pressure the mercury is drawn back, being followed by the electrolyte. The instrument is then ready for use. A microscope M containing a micrometer eye-piece is held on an adjustable support and is used for noting the movement of the meniscus. The glass tube is held firmly by a brass collar attached to an ebonite upright. Two binding posts, s, s' , form the terminals of the instrument, K being the key which short-circuits it when not in use and connects the electrometer with the binding posts when depressed. The connecting wires are placed in grooves between the two parts of the base.

This instrument is one which may be tipped in any position without injury; it is as portable as any instrument made partly of glass can be, and it may readily be taken apart for the purpose of cleaning or renewing its parts. It will respond to a difference of potential of one one-thousandth of a volt, though with proper attention to its construction and by use of a suitable microscope its sensibility may be increased ten-fold or even greater. If a pressure over a volt is applied to the terminals an electrolytic action will occur, with the liberation of a bubble of gas or the formation of a cloudy precipitate at the meniscus, depending upon the polarity. This will destroy the sensibility, but the defect can be easily remedied by compressing the rubber tube until a drop of mercury flows through, and on releasing the pressure the instrument is again ready for use. The adjustment of the meniscus on the micrometer scale may be made either by moving the microscope or by means of the pinch-cock.

The direction of movement of the meniscus depends upon the polarity, and the extent is approximately proportional, through a limited range, to the potential. This is not absolutely so, for it would entail the use of a capillary of absolutely uniform bore, which would be difficult to attain. For this reason it is almost essential to use it as a zero instrument.

The meniscus moves, not by reason of a passage of current through the instrument, but by the application of a potential difference which gives it a certain electrostatic charge. In other words, it may be said to be a condenser which automatically registers the amount of charge which it holds. An addition of resistance in circuit will in no wise decrease its degree of sensitiveness, though it will make the movement of the meniscus somewhat slower. With the instrument described, an application of a pressure of .005 volt produced a deflection of eight divisions on the scale, whether this pressure was applied direct or through a resistance of 100,000 ohms.

On pressing the electrometer key the meniscus will move very rapidly if a potential difference exists at terminals, and again on closing the short-circuit key it will quickly return to its zero

¹Read before the 15th General Meeting of the American Institute of Electrical Engineers, Omaha, June 27th, 1898. Abstract.

point without vibration. It may be subjected to almost any amount of mechanical vibration without moving the position of the meniscus on the scale.

The principal characteristics may be summed up as follows: The instrument is of very simple construction and can be made by any one fairly expert in glass manipulation. It is very light and compact, and requires little space for its operation. The instrument described weighs two pounds and occupies a space of 7" x 5" x 6". In the way of portability little more can be desired. It may be quickly set up for use, requiring no leveling, and the adjustment may be rapidly made. No serious damage such as a burn-out can occur by the accidental application of even a very high pressure. The breakage of any of its parts can be repaired with little trouble and at slight expense. One of these instruments has been in use for nearly a year, and the only repairs necessary on it was in once refilling the rubber tube with mercury. The entire absence of the effect of mechanical vibration and varying magnetic field will especially recommend this instrument. On the other hand, it can hardly be made with the degree of sensitiveness which may be given the galvanometer, and it has to be used as a zero instrument.

Measurement of Insulation Resistance.—On account of the electrometer being a zero instrument, the direct deflection method cannot be used, and a compensation method is employed the method of operating being as follows. Fig. 2 shows arrangement of connections for the test.

A known resistance R (preferably 1,000,000 ohms) is placed in series with the generator and the insulation to be measured. The electrometer c is employed in measuring the fall of potential across R by the compensation method of introducing a pressure in series with the electrometer, which shall just neutralize the pressure across R . When this has been effected the depression of the electrometer key will produce no movement of the meniscus. It is therefore necessary to have an electromotive force which may be varied at will. A resistance box of this nature was described by the author.

The data necessary to derive the value of insulation resistance then is the value of the compensating e. m. f., which may be obtained directly from the reading of the box B when a balance has been effected. Any ordinary form of primary or secondary cell may be used for pressure E . The expression for insulation resistance is

$$\text{Resistance} = \frac{E \times 1,000,000,000}{E^1 \times B} - 1,000,000.$$

The constant is 1,000,000,000 E/E^1 , and the ratio E/E^1 may be derived by means of a voltmeter, or if such instrument is not available, by balancing the smaller pressure in circuit with the electrometer and terminal $A B$ against the larger pressure connected to $c E$, the volume being 1,000 ÷ box reading.

The author also described a method for employing dynamo pressure in testing.

Values for insulation resistance may be obtained with considerable accuracy and speed, and values as high as 20,000 megohms have been measured. The limit may be made very much greater by increasing the sensitiveness of the electrometer or by increasing the value of R .

A portable testing set which I have been using for some time consists of the following parts: Chloride of silver testing battery of about 50 volts, capillary electrometer with microscope and short-circuit key, graphite resistance of one megohm, thousand-ohm subdivided resistance box, a 1.5-volt dry cell. The weight of set, exclusive of 50-volt battery is six lbs., the chloride of silver cells weighing 10.5 lbs. The range is from 0 to 5,000 megohms.

The electrometer with subdivided resistance box may be used for the measurement of direct pressures up to 150 volts with an accuracy of one-tenth of 1 per cent., provided the resistance is accurate. The standard of comparison is the standard cell of known e. m. f.

Values of current may be obtained by the use of standard resistances of large current carrying capacity, the drop through such standard being measured by connecting it in electrometer circuit. The calibration of direct current ammeters and voltmeters may be conveniently and rapidly carried out with the above arrangement.

This form of electrometer is especially suited for use in the dynamo room or in the neighborhood of moving machinery, on account for the small amount of space necessary for its operation,

the rapidity with which measurements may be taken and the entire freedom from external influences. It has been used to a considerable extent in the laboratories of the University of Wisconsin in obtaining current and pressure curves on alternating current machinery, and has proved satisfactory where other forms of measuring instruments had failed. The method of using this instrument for tracing alternating current curves is in substituting it for the galvanometer or the telephone receiver in the method proposed by Merzhon. It is superior to the telephone receiver. The degree of accuracy is considerably greater as is also the rapidity with which curves can be taken. For use in this work a microscope is unnecessary, and when the movement of the meniscus is too rapid and of a fluctuating nature due to unsteadiness of the compensating pressure or other causes, a condenser may be used as a damper. A resistance placed in series with the electrometer will also serve to increase the period of movement of the meniscus.

The above are some of the measurements in which the use of the electrometer has been tested, and the many advantages which have been found for it leads me to believe that it might be advantageously used in many other measurements in practical engineering work, especially in those where a great degree of sensitiveness is not required. In any of the modified forms of Wheatstone bridge methods for the measurement of resistance, induction and capacity it should prove a serviceable instrument. For use on shipboard it would be the ideal instrument as far as the rolling and the jars due to moving machinery are concerned.

Another property of this instrument, and one which might be utilized to advantage, is the great rapidity with which the meniscus may move under a variation of pressure. It has been shown that alternating curves of a frequency of 120 per second may be obtained by a photographic record of the excursions of the meniscus, as well as the currents of much greater frequency which the telephone line transmits.

New Transformer Plant at Buffalo for Niagara Power.

BY ORRIN E. DUNLAP.

THE first group of transformers built by the Westinghouse Electric and Manufacturing Company for the Ohio street transformer station of the Cataract Power and Conduit Company has been installed. They are four in number, three of them to be used for regular service, and the fourth to be kept as a reserve in case of accident to one of the other three. Each of these transformers is of 850 kilowatts capacity. They are water-cooled and nine feet and one inch high, while their diameter is a little over five feet. The weight of one of the transformers is nearly 20,000 pounds. The aggregate capacity of the three transformers is 2,550 kilowatts, the largest output, it is said, yet obtained from a single group of transformers. The illustrations show the outer casing of the transformers, which contain the oil, being of heavy boiler iron. They are mounted on base plates of cast iron. A cast iron cover on the top is provided with manholes to facilitate the examination of the terminals. On the primaries the star connection is used, and on the secondaries the delta connection.

The winding of the transformers is made of deep, thin coils, magnetic leakage being reduced by the primary and secondary being interleaved. Heavy end frames hold the short iron together. Outside the iron the various coils are spread apart, thus increasing the cooling surface exposed to the oil without loss of space. Spacing strips placed at intervals when the iron was set in position about the coils serve to increase the surface of iron exposed to the oil. When the transformers were made each coil was insulated and treated separately, after which they were placed in position with sheets of solid insulating material between them. Running down about half the depth of the case of each transformer are three coils of iron pipe, and through this pipe the water for cooling is circulated. Each of

the coils, which are connected in multiple, is fitted with a valve in order that the flow through the respective coils may be adjusted as desired. After this adjustment is properly made, the transformer will continue to do its work with but little further attention.

The building in which the installation has been placed is of brick, the dimensions of the transformer room being 90 by 18 feet. It is the intention, as the demand for power increases, to install three such outfits as that mentioned, and when this is done the total capacity of the station will be about 10,000 horse power. Considering the space occupied, it will be seen that the installation will be in very compact form. Were the power output of the complete installation devoted to lighting, it would supply about 120,000 lights. In the general view of the interior of the station, it will be observed that the large transformers have been placed on one side of the narrow room, while the other side is occupied by the low series transformers and low tension switchboard; and in front of this switchboard will be seen the regulators. The high tension switchboard is to be seen projecting over the top of the large transformers. In time the high tension switchboards will occupy the end of the room where the temporary installation is at present located. The voltage at which the Niagara power is transmitted to the station at Ohio street is 11,000, and it is distributed to the plants using it at a voltage of 2,200, the locality surrounding the station in which there is likely to be a large and growing demand for power. At present current is furnished to the Union Dry Dock Company, the Great Northern Elevator and the Electric Grain Elevator. Many other elevators surround the station, and no doubt some of them will soon become converts to the use of the ever constant power supply from Niagara.

The low series transformers are six in number, each of 75 kilowatts capacity. They are located in the rear of the low tension switchboard. These transformers are intended to regu-

LOW TENSION BOARD, CATARACT POWER & CONDUIT CO., OHIO STREET STATION, BUFFALO.

late the secondary voltage and have the same principle as the large transformers, while of different type and practically self-cooled.

Standing in front of the low tension switchboard are three regulators, on the exterior of which are two dials. On top of each of the regulators will be seen a handle, the movement of which in one direction operates the dial in one phase and movement in the other direction operates it in the other phase, thus alternately changing the voltage in the two phases. The wheel

to the left of the regulator operates the switch for reversing the primaries of the series transformers, the lighting of a lamp seen on the regulator indicating when the contact arms are in proper position.

The low tension switchboard is equipped with a new type alternating current breaker and the ordinary type of switch. The board is of white marble and has three panels, each control-

GENERAL VIEW OF OHIO STREET TRANSFORMER STATION, FOR NIAGARA POWER.

ling one three-phase feeder. The board has circuit breakers, switches, A. C. ammeters, A. C. voltmeters, and integrating voltmeters. The wire used in connection with the board is 0000.

The high tension switchboard is quite narrow and high. It is provided with three circuit breakers, each having a break of 48 to 50 inches. They have long wooden arms, the contact being made on the terminal, the lead being carried up in the arm. The contact is made with a copper terminal and a carbon terminal, the two forming one terminal. The break comes first on the copper and then on the carbon. As all the burning is on the carbon, the contact surface is not damaged. The different high tension currents can be thrown into the converters by a plug system at the bottom of the board. The wire of the board is No. 000.

The transformers and other apparatus of the station were installed under the personal direction and supervision of Mr. W. K. Dunlap, who is the efficient local engineer of the Westinghouse Electric and Manufacturing Company. In this connection it may be stated that the Cataract Power and Conduit Company are preparing to erect a new terminal station a short distance north of the Bullymore malt house on Niagara street, in which vicinity there is a demand for Niagara power.

A New German Electric Sewing Machine.

IN electric sewing machines constructed up to the present time, the motion has been accomplished by means of a small belt running over the pulley of the motor and the wheel of the sewing machine. In the new machine illustrated herewith, the electric motor is mounted directly on the axle. It will be seen from the figure that the shaft which gives the reciprocating movement to the shuttle and needle carries the armature of the motor. To the frame of the machine are fastened the brushes which lead the current to the commutator. The machine can be inserted in place of an incandescent lamp, as it only consumes .7 of an ampere at 110 volts and makes 1,000 revolutions per minute. The field magnets are made of soft wrought iron, giving an intense magnetic field. The armature contains a number of windings grouped in twelve sections. The small motor is shunt wound, and on the base of the sewing machine is fastened a small rheostat which is inserted in the main circuit and can be varied so as to give the machine a speed of from 180 to 1,800 revolutions per minute. The machine stands with four feet on a wooden table. The electric motor which is attached to the machine itself, has its field magnet fitted into an opening in the base. The two back legs of the machine are provided with hinges which allow the throwing open of the machine for inspection, oiling and regulation. At the right of the machine the inventor has affixed a wheel which can be turned by hand and will transmit motion to the various parts

by means of a gear wheel. At the top of the machine a small spooling device is attached, which can be set in motion either

by hand or by motor. We are indebted to the "Electrotechnisches Echo" for the above details and illustration.

French Tests of Electric Cabs for City Service.

A MOST interesting and valuable test of electric cabs for city service was carried out in Paris for a period of eleven days beginning with the first of June last under the supervision of a commission presided over by M. Forestier, inspector general of bridges and roads of the French Government, so that the test may be considered as absolutely authentic. In this test there were entered eleven carriages, all provided with the

FIG. 1.—KRIEGER INTERCHANGEABLE CARRIAGE.

Michelin pneumatic tires with the exception of two cabs, the rear wheels of which had solid rubber tires. A very complete description of these tests is given by M. Hospitalier in "L'Industrie Electrique." All carriages were provided with the Fulmen storage battery.

This storage battery, designed for automobile vehicles, as Mr. Hospitalier points out, ought to have two essential qualities. One is high specific power (watts per pound total weight) and second a high specific energy (watt hours per pound of total weight). The following are some of the figures given by Mr. Hospitalier of tests made by him on the Fulmen accumulator, type "B" 15. The battery contains 13 plates, six positive and seven negative. The plates are rectangular, 18.5 cm. high, 9.5 cm. wide, and 4 mm. thick, consisting of a grid with 24 sockets, in which the active material is placed. The total weight of the complete element and liquid is about 7.5 kg. The data of the element as referred to the total weight are as follows:

Specific current in amperes, per kg.....	3
Specific useful power in watts, per kg.....	5.3
Specific capacity in ampere hours, per kg.....	14.6
Specific useful energy in watt hours, per kg.....	26
Specific weight in kg. per kilowatt	190
Specific weight in kilogram, per kilowatt hour.....	37.5

FIG. 2.—KRIEGER CONTROLLER COMBINATIONS.

Operating at 5 watts per kilogram, the Fulmen accumulator thus has a capacity of 25 watt hours per kilogram.

Four Krieger cabs were tested and differed only in the interchangeable character of the superstructure as illustrated in Fig. 1, the cabs being so arranged that they can be readily changed from victorias to closed cabs according to the state of the weather. Each cab contains 22 Fulmen storage cells of 17

FIGS. 3 and 4.—ELEVATION AND PLAN, JEANTAUD FRONT AXLE MOTOR.

plates, each weighing 10.4 kg. per cell. The controller is arranged for eight combinations illustrated in Fig. 2. At certain speed the positions 1 and 3 produce a braking effect to limit the speed of the cab. Braking in the position 0 is more energetic and acts at low speed. The foot brake produces a complete stop. There are neither shoe brakes nor brakes of any

other kind. The stop on the heavy grades is accomplished by an expedient which consists in working the controller in a sort of tremolo movement between the positions 00 and 1. This arrangement, however, will be abandoned by M. Krieger in his new cabs for a band brake.

FIG. 5.—JEANTAUD COMBINATIONS FOR FRONT AXLE MOTOR.

FIG. 6.—JEANTAUD CONTROLLER COMBINATIONS.

The cabs of the Compagnie Générale des Transports Automobiles were built after designs of M. Jenatzy who adapted the cabs of the company to a suitable running gear. The single motor employed actuates an intermediate shaft on which is mounted the differential gear and the ribbon brake, acting in both directions. For heavy grades a mechanical speed changer operated by a lever allows the speed to be reduced in the ratio of 100 to 67.

M. Jeantaud had entered in competition a cab the running gear of which is illustrated in the engravings Figs. 3 and 4. The single motor employed is placed under the seat of the driver, driving a differential gear the axis of which is in the prolongation of the wheels when the latter are in the position of moving straight ahead. To transmit the power when the

FIG. 7.—DORÉ FRONT AXLE MOTOR AND GEAR.

wheels are not in the straight ahead position, a conical transmission gear is employed. Figs. 5 and 6 show the motor controller combinations for Jeantaud carriages.

In the test which took place the eleven carriages were required to make a daily run of 60 kilometers each, and from the table of tests it would seem that the actual consumption at the battery terminals is about 80 watt hours per ton kilometer at discharge, and 110 watt hours per ton kilometer when charging.

M. Hospitalier remarks with satisfaction that these figures are lower than those which were obtained only a year ago in the tests of Messrs. Morris and Salom, so that progress is manifest.

FIG. 8.—CONTROLLER COMBINATIONS, CIE FRANCAISE.

The test also included a determination of the cost of operation of the various types of cabs, horse, petroleum and electric. These were as follows:

Horse, per day	19.37 francs.
Petroleum, per day	28.37 "
Electric, per day	19.85 "

FIG. 9.—DETAILS, PATIN CARRIAGE.

It would thus seem that under actual conditions the cost per day of an electric cab would be about 50 centimes (10 cents) greater than that of a horse cab. Now since this sum of 50 centimes represents very closely the profit of the large com-

FIG. 10.—ELEVATION AND END VIEW, PATIN CARRIAGE.

panies, this profit would be found to be reduced to nothing. These pessimistic conclusions ought not, however, to be ac-

cepted without reserve, for since the expense of the horse cabs can hardly be reduced any more, such is anything but the case with electric cabs. The first experiments with the latter date back no further than three years in France, and the first applications in America and in England date back scarcely more than a year. M. Hospitalier hardly believes that perfection will be reached even at next year's competition. This year's test has proved that the electric cab is possible and that it is

FIG. 11.—TRANSVERSE SECTION PATIN CARRIAGE.

the only possible one. Before two years have passed he believes that the electric cab will be an economic success.

At the international exposition of automobile vehicles organized by the Automobile Club of France, concluded on July 3, a large variety of vehicles were exhibited. The engraving Fig. 7 shows the arrangement of the gear of the Doré electric cab. A series motor was employed with a vertical axis placed directly on the driving shaft and acting directly on the latter. The armature of this motor has three windings connected in series. The controller is here replaced by three hand-wheels, the first of which breaks the current and introduces varied resistances into the circuit. The second throws out of circuit one or two of the three windings of the armature; the third reverses the current in the armature for backing.

Mr. O. Patin exhibited four carriages, one of which is illustrated in the engravings, Fig. 10. The motor rests directly on the rear axle which is depressed at the centre *b* between the suspension springs so as to present a lower level to that of the ends *b*, through which pass the shaft of the motor *c*. At the centre of the carriage the shaft *b* has an oval section so as to allow the passage of the driving gear *d*. The motor *a* is held by the bolts *m* solid with the axle. The motor shaft receives its movement from the differential gear which passes through the ends of the shaft. Figs. 9 and 11 show details and a transverse section of the carriage respectively. Fig. 8 shows

FIG. 12.—PARCEL EXPRESS WAGON.

the motor controller combinations for a carriage built by the Cie Francaise. Fig. 12 illustrates one of the electric delivery wagons of which two were exhibited.

DALLAS, TEX. Mr. W. H. McGrath, vice-president and general manager of the Dallas Electric Co., is pushing a scheme for a network of electric roads radiating fifty miles around that city. Ex-Mayor F. P. Holland is also interested, and northern capital is being enlisted to carry out the scheme.

General Electric Narrow Gauge Railway Motors.

THE operation of a narrow gauge road demands a railway motor occupying a more restricted space than the motor built for standard gauge roads, while giving the same power. The General Electric Company has manufactured narrow gauge motors for some time past, and many are in actual service giving the same high degree of satisfaction as the other types of the G. E. standard gauge motors. One type of narrow gauge motor now built is the G. E. 58 which resembles in outer appearance the standard gauge motor and has an output of 37 h. p. based on the standard General Electric rating, i. e., a maximum rise of 75° centigrade in the temperature of the windings after a run of one hour at rated load, the temperature of the surrounding air not exceeding 25° C. This motor is built for comparatively heavy service in which the G. E. 52 motor would be too light and is especially desirable in cases of combined city and interurban service with moderately high speeds and heavy traffic. While designed for a minimum gauge of one meter (39¼ inches) the G. E. 58 may be used with wider gauge roads.

Magnet Frame.—The magnet frame is made of soft steel of high magnetic permeability, cast in two bowl-shaped halves. The frame is divided in a horizontal plane, and the two parts when bolted together completely enclose and protect the arma-

GENERAL ELECTRIC NARROW GAUGE ELECTRIC RAILWAY MOTOR, CLOSED.

ture, commutator, brush holders and field coils. Extension pieces are cast on the top at each end, and extend over and partly enclose the car axle. To the under side of these extension pieces are bolted the axle bearing caps bored out to support and enclose the axle linings. The armature supports are made by bolting the bearing caps to the under side of the top frame at each end and boring them to receive the linings. The bottom frame is secured to the top frame by bolts so hinged that when the rear bolts are removed the lower frame will swing down, exposing the armature and field coils for inspection and cleaning. In this position the bottom of field coils may be easily taken out, while by removing the armature caps and the bottom half of the gear case, the armature and top field coils may be easily removed.

A large opening is provided in the top frame just over the commutator, through which the commutator, brush holders and brushes can be inspected and worn out brushes replaced. Through the same opening it is possible to remove the brush holder yoke and brush holder bodies. A malleable iron cover is securely held in place over this opening by an adjustable cam-locking device and is easily and quickly removed. A hand hole fitted with a gasket and cover plate is provided in the bottom frame directly under the commutator, permitting easy access to the bottom of the motor for inspection and removal of foreign substances.

Bearings.—Appreciating that the renewal of linings is frequently the principal item of maintenance cost of a motor, par-

ticularly when designed within the limitations of narrow gauge, much attention has been given to the design of the linings and the bearings. The armature bearing linings are made of machined cast iron with 3-16-inch Babbitt metal swaged hard and bored to the proper size to fit the shaft. The bearing of the commutator end is 2 5-8-in. x 6 5-16-in., and on the pinion end 3 in. x 7 7-8 in. The supports for the linings are constructed on the outboard plan, which renders the bearings easily accessible and prevents oil or grease from working into the motor frame. The support for the upper half of the armature shaft lining is cast as a part of the upper half of the frame and is provided with a large cored recess between the inner end of the lining and motor frame. This space is utilized for a thrust collar so designed that its outer edge acts as an oil guard and turns in the recess between the motor frame and the bearings. The support for the lower half of the lining is a cap bolted to the upper frame in such a way as not to enclose the lower half of the oil guard, thus allowing free egress for the lubricant after it has passed through the bearing. The axle bearing linings are similar to the armature bearing linings and are 8 inches in length and of the required diameter to fit the car axle. The upper supports for these linings are cast with the upper frame; the lower supports are caps bolted to the upper support. All bearings on the motor are provided with grease boxes and oil cellars of sufficient capacity for thorough lubrication. The grease boxes are cast with the upper frame and are covered with

GENERAL ELECTRIC NARROW GAUGE ELECTRIC RAILWAY MOTOR, OPEN.

flanged lids held down by springs to exclude the dust and dirt. Oil cellars of ample capacity are provided in the bearing caps. The oil is fed by felt wicks or wipers, which come in contact with the shaft through holes cut in the linings.

Field Coils.—The motor has four field coils; two in each frame, placed at an angle of 45° from the split and held in place by pressed steel flanges, or spool holders, clamped by projections on the laminated pole pieces. The pole pieces are held in place by through bolts with nuts on the outside of the frame, the coils being placed in position when the pole pieces are bolted to the frame. The field coils are wound with round wire insulated with asbestos, and are substantially insulated over all with wrappings of varnished cloth and tape. The insulation between field coils and motor frame is tested by 5,000 volts alternating—sufficient to thoroughly prove the quality of the insulation. The field coil leads are brought out through the frame in a convenient manner for connecting to the car wiring, and it is not necessary to disconnect any leads inside of the motor frame when dropping the lower half for cleaning.

Armature.—The armature is of the well known iron clad type and is 14 1/2 inches in diameter with a spread of 6 1/2 inches. The core is built up of well annealed laminations and is assembled directly on the shaft. There are 33 slots and each slot contains three coils, collected together and insulated so as to form one triple coil. Hence there are 33 triple coils connected with 99

commutator bars. A small number of coils is of especial advantage when an armature has to be repaired, and the method of forming the coils into groups of three admits of substantial insulation of high quality. The insulation of the coils consists of specially prepared tape and cloth, which has high insulating qualities and is impervious to moisture. When the coils are in place on the armature core they will withstand without injury a high potential test of 2,500 volts between the windings and the core. The terminals of each coil are brought directly into the commutator segments and soldered so as to properly connect the armature coils, and at the same time form the connections between the armature windings and the commutator. The end windings are effectually protected from mechanical injury and carbon dust by the metal core heads and by a canvas dressing. The coils are held in place in the slot and on the ends by tinned steel wire bands, held together by clips and securely soldered.

Commutator and Brush Holders.—The commutator is 10 inches in diameter. Its segments are 4 3/8 inches long with a wearing depth of 1 inch and are insulated from the shell by cone clamping insulations of the best quality of pressed mica. The segments are of the highest grade drawn copper of uniform hardness, and are slotted at the back for the armature leads. The mica between the segments is of a somewhat softer quality than that used in the clamping insulations, to insure an even wear with the copper segments. The completed commutator is tested by 5,000 volts between segments and shell and 500 volts between adjacent segments. Particular attention has been given to the matter of commutation, and under normal conditions the commutator will run with practically no sparking.

The brush holders of cast brass are constructed to receive two carbon brushes per holder. The brushes are 1 3/8 in. x 2 1/4 in. x 1/2 in. They slide in finished ways and are held in place against the commutator by independent pressure figures, which give a uniform pressure to the brushes throughout their entire working range. The brush holders are clamped to a hard wood yoke, carefully treated with a moisture proof insulating compound. The brush holder yoke is bolted to the top magnet frame, and is so arranged that it may be removed through the opening in the frame over the commutator. All the leads from the motor to the car body are brought out through the rubber bushed holes in the magnet frame at the front of the motor, thus facilitating wiring of the car.

Suspension.—G. E. 58 motors are adapted to nose, yoke or side bar suspension. The yoke suspension is especially recommended, as the weight of the motor is carried on springs placed upon the side of the truck frame. Lugs are cast on the upper magnet frame, to which the suspension bar is bolted; the lower half may, therefore, be swung down into the pit without disturbing the upper half, which remains suspended from the axle and yoke. When the motor is mounted on 33-inch wheels, the clearance between the bottom of the motor frame and the top of the rails is 4 1/4 inches; the clearance between the bottom of the gear case and the top of the track is 4 1/4 inches. The motor without gear or gear case weighs 1,865 pounds and complete, with both gear and gear case, weighs 2,150 pounds.

Electric Railroading in Eastern Massachusetts.

Few people have an idea of the magnitude and rapid growth of electric railway traffic in Eastern Massachusetts and Rhode Island. A few facts from Derrah's Street Railway Guide, just issued, will surprise even those who are accustomed to take long rides in the electric cars. The number of miles operated by the street railways of Massachusetts and Rhode Island, included in Derrah's Guide, is 1,368.25, out of a total of 1,738.50 in both States. The number of passengers carried last year by the street railways included in the Guide was 312,000,000. These facts indicate the need of a work of this kind, and in addition to the complete tables showing routes, rates of fare, distances, etc., the edition this year contains more than 160 pages of reading matter descriptive of all the principal points of interest along lines of the street railways. This matter will be found of great value to those who make excursions on the trolley trips in summer. The volume is of a convenient size for the pocket, and is handsomely illustrated with some 90 half-tone views of places of interest. The author of the Guide has been connected with the West End Street Railway Company for the past nine years, and has made a special study of the street railways throughout New England. The Guide has the indorsement of the Massachusetts Street Railways of the State. It is published by Robert H. Derrah, 115 Devonshire Street, Boston. The price is 15 cents.

Vol. XXVI. NEW YORK, AUGUST 4, 1898. No. 535

Municipal Telephony in England.

AS our readers are probably aware, a good deal of evidence has been taken recently in England before a select committee of the House of Commons on the subject of "municipalizing" the telephones. It cannot be said that the evidence has revealed anything very new, although a great many witnesses have been called. The fight is a rather curious one in itself, being triangular, and not likely to occur in this country, at least not at present, although there is no telling to what lengths municipal socialism may not carry some of our citizens, such as those who denounce Tammany hotly and next moment propose to create a huge municipal railway system for Tammany's special delectation.

It will be remembered that in England the post office has a telephone monopoly and does some telephone business, but that the National Telephone Co., under a license now running to 1911, does practically the telephone exchange work of the country, even when competing against the Government. For example, in Liverpool, the post office has 14 subscribers, while the National Company has something like 10,000. Now, however, a movement has sprung up with the object of enabling the municipalities to own and operate telephone exchanges, and over this proposition the contest wages. Some of the municipalities want it, some oppose it; and the General Post Office does not favor it at all, if we follow the testimony. Mr. W. H. Preece, the well-known chief engineer of the Government Telegraphs, in his evidence, just reported, puts the official opinion in this shape: "The demand for the municipalisation of the telephones was founded on three assumptions, each of which he submitted, was erroneous, namely, that the post office was unable to give an efficient telephone service; that the National Company was unable to do so, and that the municipalities could give one both efficiently and economically." At the same time, Mr. Preece avowed his belief that the Government could compete with the National Company if the terms of competition were equalized; "whereas the National Company not only had energetic canvassers but were allowed to employ all the usual commercial means to extend their business."

Two points become very obvious in this investigation. The first is that some of the municipalities seek to intrude into a field already well covered, and one in which it would certainly be preferable to let the Government manage if the National Company is to be crowded out, a consummation devoutly to be dreaded. The other point is that the municipal plants would be purely local, and that the business of inter-connections would be confusing to the best clearing house system ever devised. You might just as well try to operate the telegraph on a local basis, without trunk lines. The proposition is so absurd it needs only to be stated to reveal all its crudity and wildness. In this country, among the greatest difficulties that the numerous independent

telephone companies have to contend with is the absence of trunk lines for inter-communication, so that we see a steady movement constantly in progress to supply the deficiency on some kind of combination plan which in the long run must mean the formation of territorial operating companies such as those of the Bell system, in turn supplemented by long distance lines open to them all, on a pro rata plan of earning.

The Search-light and Electricity in the Navy.

IT is certain that one of the results of the present war with Spain will be the greater use of electricity on board men-of-war, and particularly on our own. The searchlight has assuredly proved its value. It made Cervera come out in the daytime, for, according to the confession of the Spanish officers themselves, it was no use trying to dodge the beams of light that made the exit each night brighter than it was by day. There was no dodging that insistent beam. We note that a distinguished English critic, Lieut. G. Armstrong, R. N., thinks that Admiral Cervera had a fine chance to torpedo, as "the Americans appear to have had no picket boats watching the harbor, and their ships were without nets." The splendid efficiency of the searchlights is a sufficient answer to whatever is true in that criticism.

The new battleships will have a good deal of electrical apparatus for the operation of the guns. It is now evident, we believe, that motors are the best devices for handling turrets, guns, ammunition hoists, etc. Besides, a broken wire can be spliced in a second, where a ruptured pipe could not be mended at all. The means of communication, of steering and range finding have also suggested various improvements, all of which will be studied out. Even the newer things will have their uses, some now unsuspected. It is not extremely impossible that shell before going to the guns may be X-rayed and show up any defect, for it is known that many shells were useless and the defects were necessarily within. We have heard also lately a good deal about the use of the megaphone between the ships and of ceaseless flag and lamp signaling, but not a soul has succeeded in enabling the ships to talk electrically without wires between them. Surely it is possible now to do this. If not, why do such geniuses as Edison, Tesla and Marconi live?

Avoiding Collision at Sea.

THE old saying that "When a child has fallen into a well, they think about covering it over," has again found its echo in the means suggested for avoiding collisions at sea, after the terrible accident whereby the French ocean liner *Bourgogne* was sunk by colliding with the *Cromartyshire*. Hundreds of unfortunate passengers and members of the crew of the former vessel found a watery grave, while the small number of survivors had horrible tales to tell of butchery and disgraceful scenes. This terrible catastrophe, unparalleled in the annals of modern transportation, and one which has shocked the entire civilized world, has given cause for reflection and has put judges, pessimists and inventors to work, fixing responsibility and devising means whereby a repetition may be avoided. Fortunately it is not within our sphere to pass judgment on actions as inhuman as those of which members of the *Bourgogne* crew or perhaps sailor passengers in the steerage are accused. But does the placing of this blame on the sailors for lack of cool-headedness and fellow-feeling exonerate the companies into whose hands the passengers entrust their lives? This is a pertinent and timely question which will have to be answered sooner or later. As the traffic on our ocean highways increases, as well as the speed and number of ships, collisions will occur, due to the elements, personal neglects and errors, and seemingly unavoidable causes. But it is for the companies to find ways and means whereby the liabilities of collisions will be reduced and to install adequate life-saving devices. To discuss all these questions minutely as each one deserves would fill volumes and is outside the province of our pages, and we will refer simply to the question of the prevention of accidents, leaving that of cure in the hands of the companies and to the judgment displayed by officers, crew and passengers at the time of the accident. While many devices have been in use on board vessels for announcing their approach to each other, some of which have proven fairly satisfactory under favorable conditions, none, judging from the frequency of mishaps, have as yet been devised which will under all conditions make the presence of one vessel known to another. This is due not so much to the transmitting devices, as to changes in the transmitting medium and inefficient receiving apparatus. The rea-

sons for this are pointed out admirably in a paper by Mr. Herrman Herberts, on another page of this issue. The author goes a step further than merely criticising the old methods, in suggesting one which appears to be both novel and worthy of careful consideration. While it has been known for years that the heat radiated from a ship might serve as an indication of its approach, using the thermopile to receive the radiations, Mr. Herberts has devised an ingenious, delicate and what appears to be a fairly reliable arrangement for the use of a thermopile in connection with a galvanometer. Two complete sets of apparatus, which would indicate the approach of an iceberg as well as of a ship, are required on board of each vessel, one at each side of it. They must be shielded from outside influences such as warm or cold currents of air and water, if such is possible, and must be carefully and nearly constantly watched during foggy weather and at night. The apparatus must be sufficiently sensitive to indicate the approach of a sailing vessel, without boilers and with few persons on board to give out such heat, as might be expected to be radiated from large ocean greyhounds. These and many more are the severe conditions imposed upon this newly devised system, which regardless of its possible limitations, deserves to be placed in the category of useful and humanitarian suggestions. Who knows but that the difficulties which now may seem to beset it, may be removed by conscientious and painstaking experimenting and diligent thought, or that it may perhaps lead in the right direction for the preservation of life and property at sea.

Gold from the Sea.

THE daily papers are full of sensational accounts of the operations of the Electrolytic Marine Salts Co. and the sudden disappearance of its vice-president, Rev. P. F. Jernegan, from the scene, with a satchel full of Government bonds into which he has converted a large amount of ready cash. It was known in this part of the world that a company was trying up in Maine to extract from the sea the gold that is reputed to exist there in about the proportion of one grain per ton of salt water, but it had not been realized that a big speculation was based on this, and that a large number of unwary people had bought stock in the enterprise all through New England. The capital was \$10,000,000 in \$1 shares, and of all sales of stock Mr. Jernegan was to get 45 per cent., the rest being applied to working the "invention," which was a secret. Just how much stock was actually sold does not appear, but it reached at least \$1,000,000, and Mr. Jernegan's share of \$338,000 is apparently what has gone to buy his wad of choice bonds. Up at North Lubec, Me., the company had a plant right on the mother lode, i. e., the Atlantic, with 240 "accumulators" at work to throw down the gold and silver. Every week a \$2,000 brick of extract has come along, purporting to be the product of the plant, although it is now shrewdly suspected that one or two bricks have been playing the part of a theatrical army on the stage. When the accumulators were inspected last week after Mr. Jernegan's flight, each one was found as bare as Mrs. Hubbard's cupboard, in spite of the fact that they were rated to produce \$1.25 every twenty-four hours, and did their work so miraculously well that the weekly gold brick was always about the same weight and value. The cost of production was only \$300 per week.

The North Lubec works are now shut down; the thrifty New England investor is all anxiety and tears, and the air is full of wild rumors, but the Rev. F. P. Jernegan will doubtless explain everything satisfactorily when he lands, to the detectives who are waiting for him at Havre. One is reminded of the Friend Electric Sugar Refining swindle which played havoc in New York with the gullible public, and which did not even have a basis of physical data to rest upon. There are well-informed engineers who believe that if the plant were only big enough, the sea might be profitably attacked with right methods and made to yield its precious metals, as it does its salt; but it seems unlikely that Mr. Jernegan had got the approval of any authoritative expert for his work. We know that our own letters of inquiry went unanswered, and it is probable that the "secret" was never divulged to anybody.

Mr. Jernegan is said to have stated before he left that he was going to buy in Europe electrical machinery that he could not get here. It is a pity he did not specify what it was. Perhaps he was unable to do so. We do not know of any such apparatus made in Europe that is better than any made in America; and Mr. Jernegan's statement should have aroused suspicion amongst some at least of the shrewd business men whose names are mentioned as being his associates.

Even should the reverend scientist succeed in establishing his fair fame, we made bold to say that his enterprise is one more warning that people should not invest in any electrical or mining enterprise until they have secured the advice of responsible authorities, whose fee will be well worth the paying.

Women Car Conductors.

SOME weeks ago we made note of the fact that Mr. Myers at Chillicothe, Ohio, was employing women as conductors on his street cars, and was satisfied with the results. Mr. Johnson at Madison, Ind., appears to have been less happy in his experience, and it is stated that in consequence of the same experiment there, the patronage of the cars has fallen off considerably. "Merchants, landlords, and in fact all classes of citizens are protesting, and the labor organizations are leading the opposition with all their strength. In every aspect of the case the change is looked upon as an innovation that public opinion cannot and will not tolerate." The news comes also of a trial of women conductors at Vincennes, Ind., "as a matter of economy," the wages paid the girls there being \$20 per month. No general disturbance appears to have resulted in Vincennes yet, but there has been, naturally, "considerable talk and some indignation on the part of old employés."

It seems hard and unfair to exclude women from any employment commensurate with their ability, but one would imagine that the rough, trying ordeal of street car running and the collection of fares from all manner and conditions of people is not quite the best work for women to choose. Of course, if all the young men in the country had gone to the war, it would appear absolutely necessary to employ young women; but the number of soldiers required to lick the Spaniards into submission is really insignificant. If the question is solely one of economy, it is certainly better to operate the road with women than have no cars at all. At Madison, public opinion has pronounced against the novelty in a severe manner, but we cannot believe that in any American community, women trying to earn an honest livelihood will be treated otherwise than with respect and civility. It will be remembered that when women entered the telegraph service there was a tremendous feeling against the innovation, but they have long ago lived down all that. In other countries where women are employed on railroads they appear to be well treated by the public and to get along pretty comfortably. It must be, after all, a matter of public opinion. If American people make up their minds that women are not desirable as employés in the traction field any more than behind saloon bars, that will settle it.

So far as we know, women have not invaded at all the field of central station work. A case was reported last April of a woman running an electric light plant at Logansport, Ind., on the sudden resignation of the engineer; but we believe it was only a temporary assignment. Yet, women are often engaged on much harder work, and much more disagreeable jobs, than can be found in a clean and neat lighting plant, where they are not under the necessity to have anything to do with the public. Perhaps it is too much like the retirement and isolation of domestic service to be inviting to women; whereas we can readily understand that for a bright, strong, good-natured girl the prospect of being always on the go upon the cars and of seeing what happens around town, with the opportunity to encounter friends or become acquainted with marriageable young men, might have many attractions in spite of low salary. As between factory life and domestic service, few girls hesitate, and we opine that most of them, if physically equal to it, would consider street car conductorship superior to both.

WE understand that Manager Naylor, of the electric light plant at Wadena, Minn., placed red and blue electric lamps on top of the water tank to give notice of the way battles were going in the war. If Spain were winner, the red lamps would be turned on; if the United States came out on top, the blue would announce the glad news. Mr. Naylor has several red lamps for sale, good as new.

IN view of the growing interest in automobiles, principally those propelled by the electric current, and the impetus which this new art has received on the other side of the Atlantic, especially in France, we print on another page a report of the recent exhibition of automobiles in Paris. This report is an abstract of a more exhaustive one by M. Hospitalier, the well-known French electrical authority.

Allegheny County Light Company, Pittsburg.

THIS company was organized in 1881 and operates the only central lighting station in Pittsburg and Allegheny. In order to care for its growing business, the company has recently, after successive moves and alterations, concentrated its entire equipment in a splendid new building at Thirteenth and Etna streets, near the Allegheny River, and comparatively near the center of distribution (the field covering a territory ten by eight miles in extent), but even now it is engaged in replacing generators and engines that were recently thought to be up-to-date with more modern and more efficient equipment. The latest installation includes four direct coupled units, each of which consists of a Westinghouse vertical type compound condensing engine, of 2,000 nominal horse power, and a Westinghouse two-phase generator of 1,500 kilowatts capacity, equal to the 20,000 16 c. p. lamps. The armature of these machines, which are among the largest yet erected, measures 16 feet 8 inches in diameter, and weighs 40 tons, the speed being 120 revolutions per minute. The current at 2,400 volts is collected from a four ring collector which is located between the generator and the outside bearing. For the outlying districts, one of which is five miles from the station, transformers are used, the first being a step up to 5,500 volts, three-phase, and down to 2,400 two-phase. It is the intention to synchronize the machines and run them in multiple, and for this purpose dash pots are being added to the valve gear of the engines, as the single weight governor is found to be too sensitive for synchronizing properly. A duplicate set of steam pipes is provided throughout, and each valve is backed by a second to provide against possible contingencies. The valves consist of steel bodies and the flanges are of forged steel, milled and finished, making a specially tight joint. The exciting current for the field coils is obtained from three direct coupled units, consisting of Westinghouse engines and generators, two being of 75 kilowatt capacity, the other of 40 kilowatt under a voltage of 250. The cables from each machine lead directly into the basement to the resistance coil, then up to the switchboard on which the switches are operated by a pneumatic device from levers located at a safe distance from the board.

The arc light machines, of which there are 32 in this station, are of the Brush type, each of 60 light capacity. These are driven by belts from Westinghouse compound engines, three being placed in tandem to each engine. These as well as the alternating current generators are to be replaced with large units, and so equipped that they will deliver current of any required capacity. While the Brush machines are said to be out of date, it is not from any deterioration in efficiency, for even after long service they are regarded by the superintendent as efficient as when first installed. When a few of the armature bobbins have been renewed, it is the practice to re-wind all, in order to maintain the armature in perfect balance. The principal auxiliary steam equipment of the engine room consists of a Worthington high cone jet condenser of 6,000 horse power, it being one of the largest, if not the largest, condensers yet installed in a lighting station. Water for condensing purposes is derived from a well which is 12 feet in diameter and 45 feet in depth, to which the water is led through a 4-foot brick tunnel which extends from near the bottom of the well 592 feet under the bed to the channel of the river, which terminates in a filtering crib. This tunnel was recently illustrated and described in *The Electrical Engineer*. The engine room is also equipped by a 30-ton electric Morgan crane, which spans the structure and serves to handle any part of the machinery.

The steam generating plant consists of 16 water tube boilers of the Babcock & Wilcox type, rated at 6,000 horse power, and these are located half on each floor of the boiler room, as the boiler house is a two-story structure, heavy iron posts being provided for supporting the weight. The boilers are fed by Roney stokers, and the coal, which is hauled by carts from boats in the river, is elevated into nine ton storage tanks located on the roof of the boiler house, from which it descends by gravity

to the stoker. The company has also provided a storage yard in which 3,000 tons of coal are kept on hand to provide against any emergency in case high or low water should interfere with the shipping facilities. The station consumes about 150 tons of coal per day.

The new building is of brick, fireproof, and occupies a ground space of 100 by 400 feet. The engine room is 100 by 200 feet and 34 feet in height. The walls are of white enamelled brick, while the floor is of tile, giving it a clean appearance, a condition seldom found in a Pittsburg establishment, due to the prevalence of smoke from the numerous furnaces. The same cause renders the atmosphere cloudy, which calls for electric lighting service both day and night for a good part of the year. The building contains besides the power station proper the business offices of the company, repair shops, draughting room, testing and laboratory departments, store room and an electric kitchen and dining room. In the latter, the noon day meal for the office force is served, all the food being cooked on electric kitchen appliances, from the American Electric Heating Corporation, of Boston. Electric fans located above the table provide for free circulation of air, and help to give it its name, the "Electric Dining Room." The present output of the station is 2,500 arc lights of 2,000 c. p. each, and 115,000 16 c. p. incandescent lights. Considerable current is provided for stationary motors, and during a part of the day current of 500 volts is supplied to one of the street railway systems. Among the repair tools may be noted a storage battery hand cart in which a number of cells are constantly kept charged and which is used for a lighting current when it is necessary to make repairs in the subways and manholes. This is a precaution to prevent an explosion of accumulated gas which is sometimes destructive when open lights are used. The affairs of the company are under the efficient management of Mr. G. H. Blaxter, vice-president, who is assisted by Mr. W. J. Hunker, superintendent. Mr. Hunker has been with the company almost from the start and has conducted the various transformations in the power equipment. He wonders if he will ever have the opportunity of operating a plant that is not undergoing enlargement.

Practical Features of Telephone Work.—XVIII.

BY A. E. DOBBS.

IN a former chapter on instrument specifications, preference is given to the Hunning type of transmitter, not because it is the best, for I regard it as a rather inefficient one, but because it is free from patent litigation, if any of them are, and if properly made will do good service, and needs no adjustment or repairs while in ordinary use. One of the objections to it is its high resistance, which cuts down the battery current while the mass of carbon granules is not as sensitive to slight variations as the old-fashioned Blake, so that voices cannot be so readily recognized. Were it not for the fact that on account of blackening at the contacts the use of the Blake is restricted to a single cell of battery, it would be an ideal transmitter for either short or long distance work.

The modification of the Hunning, known as the "solid back," is an improvement, but care should be taken to avoid detail patents.

One company in Marietta, Pa., cuts down the resistance of the carbon granules by plating them with gold and silver. This bi-metallic combination should make a powerful talking instrument provided that experience shows that the granules do not oxidize. In order to get the best results I should think the granules might be mixed with those of ordinary carbon in, say, equal parts.

INSTRUMENT AND LINE TROUBLES.

It is to be supposed that every lineman knows how to "hunt trouble," but one or two hints may not be amiss.

In open lines it is best to first go on the line and listen, for any telephone man who knows his instruments and lines, can tell by listening, and blowing gently on the transmitter, about how far off his trouble is, either on grounded or open lines.

Thus, in an open line, if the line is "dead," with not a particle of escape or induction coming back to the ear, he knows that the trouble is nearby, and acts accordingly. If, however, he can hear a slight inductive disturbance, he knows that it is outside of the office cables, or a quarter or half a mile away, and familiarity with the exchange and the instruments in use will enable him to guess very closely as to where the trouble is.

All lines, however, will not act in the same way. Thus, lines running through trees will act differently from those that are well insulated, and those alongside of a trolley road will be more noisy than those in other parts of the town; but practice will enable him to tell the difference.

With grounded lines the case is reversed. If the transmitter comes up loud and clear, without any induction, the trouble is nearby, and the amount of induction on the line is in proportion to the distance. This method also requires practice.

In New York City in the early days when there were hundreds of housetop fixtures, there were men so expert in this kind of a thing that they could almost walk to the block where the trouble was located, and as climbing onto six-story buildings took time, a man was judged very largely by his ability to clear trouble with the least amount of work.

What is known as "resistance trouble" is caused either by a loose connection which will be indicated by the lines opening at intervals, or by insufficient contact, which makes the conversation have a very faint, far-away sound, as when a joint is made in rusty or badly corroded wire without cleaning. To locate this trouble generally requires the services of two men, one to listen and make tests, while the other goes along the line to the points directed.

In the first place short circuit the subscriber's instrument, and if the transmitter "comes up" loud and clear, it is plain that the fault is outside. Next try another short circuit, or ground,

FIG. 52.

outside the subscriber's premises, and try the instrument again, which will show whether or not the house wiring is all right.

Then let the second man start, either at the exchange or the sub-instrument, as shown in Fig. 52, and move from point to point, as at A, B, C, until the trouble is located between two points, when the range may be narrowed down, meanwhile carefully examining all connections, until the bad one is found. The second man may use a telephone and listen himself, or he may merely short circuit, or ground the line, depending upon the first man for information as to results. Of course if the line is grounded or short circuited, the first man must depend upon his skill in listening, to locate the trouble.

A loose connection is sometimes hard to catch owing to the fact that it may not show up for days, then suddenly open up without warning, only to appear all right again when the trouble man tests it, and in this way keeps the office force "guessing" for a week or two.

This trouble is often found in the switch hook, and for this reason always test the instrument first.

It is also frequently found in cable and office terminals that a loose screw or unsoldered tip is the cause. It will sometimes be found in a faulty switch cord, or a dirty spring jack. It may also be found there, especially after a thunderstorm or a or in the secondary winding of the induction coil, and in some instruments where the line circuit goes through the generator shaft, it may be found from loose or dirty springs at that place.

In some switchboards where the drop is left in circuit, it may also be found there, especially after a thunderstorm or a visitation by other foreign currents.

Therefore, while there is a chance that this trouble may be in the line, there are several chances that it may be in the instrument, switchboard, or distributing board, and these should be tested first.

In some of the new exchanges a great deal of trouble can be traced to the excessive use of fuses in the line.

In one exchange there were fuses at both cable terminals.

and still another in the instrument. This, of course, protected both instruments and board very thoroughly, but the annoyance and trouble from this batch of sensitive fuses cost the company many times the price of an occasional drop.

Three fuses in the line are enough, two at the distributing board (both sides of the circuit) and one at the instrument, which should satisfy the most exacting insurance inspector and afford all needed protection. Of course, as explained in a preceding chapter, ground arresters can be placed wherever desired.

The first thing a trouble man should do is to become familiar with the instruments in use, and for testing purposes the ordinary instruments may be divided into four parts:

1st. The generator circuit. If in trouble, will not ring the exchange, though the bells can be rung from there. Remedy: Test by placing a finger and thumb on terminals nearest the armature coil, turn the handle and "feel" for current. Most magneto generators have a movable shaft which, when the handle is turned, is pushed over against a spring contact which puts the generator to line. Trouble is often found here.

2d. The ringing circuit. This includes the bells and the "down" contacts of the switch. Trouble: Does not ring, though the generator may, or may not, ring the exchange. Remedy: Open one side of the bell magnet circuit, then turn the handle and "feel" for current, placing the thumb and finger so as to shunt the bell magnets. If the current comes up all right the trouble is with the magnet spools, for it can't be anywhere else. If this test shows a strong current, place the thumb and finger in series with the spools and in this way find out whether it is an "open" or short circuit. In some instruments the frame of the bell is connected in circuit so that another "ground" on the frame would cut the bells out and this will often be found in the wire ends joining the two spools together getting in contact with the frame. If no current, however, is obtained in this test, examine the switch contacts and test back toward the generator.

3d. The secondary circuit. This includes the secondary coil, and in most cases an up-switch contact, receiver, cord and line. Trouble: Does not talk, though it can ring the exchange or be called from there, but so far as talking or hearing is concerned, the line is "dead." Remedy: Examine the contacts, test cord, receiver and coil, till the trouble is found.

Note: In some cases the receiver is left in series with the ringing coils when the hook is down, in which case it cannot be included in this circuit, as a broken cord opens the whole line.

4th. The primary or transmitter circuit which includes the battery, the transmitter, the primary coil, and the up-switch contacts. Trouble: Can call the exchange and hear perfectly, but cannot be made to talk. Remedy: Examine carefully the battery and wires leading to the coil and transmitter. Take a hand telephone and, beginning at the battery, follow up the circuit as long as the battery clicks, until the trouble is located. Sometimes a cross between the primary and secondary coils will produce this effect.

The first and second sections of the above apply only to those instruments in which the ringer coils are in series with the line. There are other instruments with direct current instead of alternating generators, or with the ringer coils bridged across the line instead of in series.

In such a case insist on having a diagram from the manufacturer, or else take the instrument and study it till thoroughly familiar with it, following out the divisions indicated above.

Sometimes a transmitter will not talk well from having too much or too little carbon in it.

In order to test this, blow your breath gently across the edge of the mouthpiece and into the transmitter, and when the sound breaks very slightly, the transmitter is as nearly right as you will get it, and a little practice will enable you to test very accurately and rapidly. Beware of too tight an adjustment if you would get good results.

I have seen transmitters so full of granulated carbon that the only way they could be made to talk was to rest the point of the chin against the mouthpiece so that the direct vibration from the vocal organs (the chin is not exactly a vocal organ, but it is connected directly with them and vibrates when speaking) might shake up the mass.

OTHER ITEMS.

It is not a good plan to put two or more telephones in

series on a single line, as the self-induction of the magnets raises the resistance of the line to many times the measured resistance of their coils. A better plan is to buy instruments with 1,000 ohm coils and bridge in on the line, and party lines should be limited to six telephones at the outside, and four would be better still.

In cutting in an auxiliary bell, do not loop it in on the main line, as you will then have it in series when the line is in use. Instead, loop it in on the bell circuit, by bringing the wires inside the box and cutting the bell loop between the right hand binding post and bell. By doing this you will have the auxiliary bell cut out, or shunted, when the hook is up.

This rule also applies to drops used for this purpose. With bridged bells where it is thought necessary to bridge in with a 1,000 ohm auxiliary drop or bell, bring the wire inside the box and bridge across the bell loop, that is, if the bell loop is cut out during conversation.

A 100 ohm drop will generally work in series with a 1,000 ohm bell, however, as the exchange generator will easily furnish current for both.

In connecting telephones in multiple or bridged form, it is a matter of some importance that the generator is able to ring them all clearly, and the only way to do this is to connect several of them together in the shop and try them there; in this case the generator should be tried on nearly twice as many as it will have to ring in practice, in order to balance line resistance, etc.

There is many a generator that will ring one bell through 40,000 ohms resistance, which would not ring four bells in multiple through 1,000 ohms of line resistance, because while the voltage is high the quantity is very small, and it should, in this case, be tested on at least eight instruments in the back shop.

The number of bells a generator will ring depends largely upon the number and size of the magnets and the winding of the armature.

Independent Telephone Combination In Iowa.

A MOVEMENT is on foot for the consolidation of all the independent telephone toll lines in the State of Iowa, under one management, and the merging of the several companies into one big organization. Propositions for the proposed consolidation have been forwarded to the management of a number of lines with every indication that they will be accepted, and a meeting to outline the plan of consolidation will be called in Des Moines at an early date. The nucleus will probably be the Central Telephone Company of this city, says the "Leader."

The Central Telephone Company was organized by local capitalists, ostensibly to build a toll line from Des Moines to Oskaloosa, with a couple of short branches. This line is nearly completed, but now it is stated on excellent authority that a consolidation is in sight, and that the people who backed the Central are backing the new scheme and urging its consummation. There are now no less than thirty companies in the State operating independent telephone lines. These occupy small areas. Each is under a separate management, and a double toll system exists where two or more lines must be used to reach a designated point. There is also the inconvenience of connection between lines and under separate managements, and many other drawbacks to the operation of the independent lines on a basis that will enable them to compete with the old system. The Bell has the advantage that it reaches every portion of the State by its own system without double toll charges and without connections through separate exchanges. Then the independent lines are at a disadvantage in some localities because they are not connected one with the other. By a consolidation, it is claimed, all these difficulties could be overcome, and the independent people would be placed in a position to compete for all classes of business.

The proposition is said to be to considerably increase the capital stock of the Central or some similar organization and issue it in exchange for the stock of the other companies at a ratio to be determined by a board of appraisers to be appointed at a joint meeting of the companies who will investigate the several lines, determine what they are worth and what the volume of their toll business is and take into consideration other items relating to their worth as a portion of the consolidated system.

It is said that the independent lines now reach eighty-five out of the ninety-nine county seats in the State, and have over

1,200 toll stations, practically as many as the Bell Iowa. Many of the lines are equipped with copper metallic return circuits, others are being equipped, all of them are well built and from every point are as good as the Bell lines. If the consolidation is effected the first aim will be to secure connections with all independent telephone exchanges in the State, and ultimately to extend the lines to all the principal points, reaching the county seat towns, from which the greater volume of business is transacted, first. In the end the company may engage in the telephone exchange business and build or acquire a number of exchanges. This feature of the business is not included, however, in the proposition for consolidation, and would be a matter for future consideration, but a plan is proposed by which the new system, if it is organized, will have access to all the independent exchanges.

CANTON, S. D. The Canton Co-operative Telephone Co. started its exchange on June 28. It has a 100 drop board furnished by the American Electric Telephone Co., and 87 telephones now connected up. It is making extensions to Beloit, a distance of $2\frac{1}{2}$ miles, and Beresford, 22 miles. The house rate is \$1 per month, and office rate \$2. The capital stock is \$10,000. The officers are C. E. Judd, president; F. H. Bacon, secretary, and C. M. Sedley, treasurer.

Victor Telephone Apparatus.

THE telephone apparatus manufactured by the Victor Telephone Mfg. Co., 166-174 South Clinton street, Chicago, Ill., has been attracting a great deal of attention of late on account of its many points of efficiency. The double pole receiver made by this company, shown in the illustration, has a very powerful compound magnet fitted in a hard rubber case, and is supplied with a Victor special device for keeping the poles constantly in the same position with the diaphragm. The

VICTOR TYPE "A" TELEPHONE SET.

magnet spools are wound with No. 36 silk-covered wire, all connections being soldered and thoroughly insulated. The long distance adjustable arm transmitter of this company, also illustrated, is of very neat design, and is superbly finished and ornamented. The transmitter head is made of hard rubber, so

as to prevent the absorption of moisture, and the consequent packing of the granules. The instrument is very sensitive, powerful and clear in articulation. A 500 ohm induction coil accompanies the instrument, of which over 10,000 are said to be in use.

The complete outfit shown, called the Victor "A" has been especially designed for both long distance and exchange work where a strictly first-class instrument is desired. The wood-

VICTOR LONG DISTANCE ADJUSTABLE ARM TRANSMITTER.

work is quartered sawed oak, neatly carved and highly polished. The battery box is constructed to hold from one to three cells of ordinary wet battery, one above the other, doing away with the ordinary wide battery box. The generator and ringer are made of approved designs with the best material and workmanship that can be procured, and are guaranteed to give a powerful ring through 15,000 ohms resistance.

The Victor transmitter is of the long distance type and is mounted on an adjustable arm. The Victor "B" set is very similar to the "A" set just described, except that it is wired for multiple or bridging work and has a special ringer and induction coils for toll line work, for which it is specially recommended. Both these sets are supplied with the Victor double

VICTOR DOUBLE POLE RECEIVER.

pole receiver described above. The switchboard made by this company has many valuable features, such as strength, durability of parts, solidity of construction and beauty of appearance, fine workmanship, the best material, rubber insulation and soldered connections, freedom from induction and cross talk, rapidity and ease of operation, economy of maintenance, simplicity of changes and removal of parts, ease of placing bridge coils and rapid ringing device.

The "express" switchboards are straight metallic but may be used for common return wire, in five-number jack and drop self-contained sections, from which the 100 sections are built up. It is claimed that the Victor switchboards possess numerous points of superiority and merit. They are put up for either metallic or single-wire circuits in any size up to 3,000 drops.

A large number of these and other Victor telephones and boards have been installed in exchanges, factories and homes throughout the world, and have given entire satisfaction.

ASHLAND, KY.—The Lawrence Telephone Company has increased its authorized capital stock to \$24,000. It has the system of the Western Telephone Construction Company, a board of 300 drops, 304 subscribers and 20 miles of toll line. The circuits are hard drawn copper and Bimetallic Company's wire. The rates for residences are \$1.50 per month, and for business offices, \$2. W. B. Seaton is president, J. L. Anderson, vice-president, and F. E. Hayward, secretary.

Important Telephone Patent Decision—The St. Louis Kellogg Switchboard.

A PATENT decision of great importance to the independent telephone movement, was rendered by Judge Showalter, of the U. S. Circuit Court at Chicago, July 29, in the case of the Western Electric Company vs. Kellogg Switchboard and Supply Company, in which the complainant sought to restrain the defendant company from installing a switchboard for the Kinloch Telephone Company of St. Louis. Judge Showalter denied the preliminary injunction asked for.

The Kinloch Telephone Company has established an exchange in St. Louis in which it has laid about 105 miles of conduit, expended over \$1,000,000, has about 5,000 instruments already installed, and the switchboard will be completed and service for subscribers will commence within a short time.

The complainant applied for an injunction on the Firman patent, which expires on January 19, 1899, and the validity of which has been recently sustained by Judge De Haven, of the U. S. Circuit Court, Northern District of California, upon limited lines. The decision in California has been appealed to the U. S. Circuit Court of Appeals, and relying upon that decision, the complainant here sought to obtain an injunction and thus prevent the Kinloch Company from beginning operations, as had been planned.

It was affirmed by the affidavits of Prof. Elisha Gray, Prof. Carhart, of Michigan University; Milo G. Kellogg and F. W. Dunbar, that there was no infringement. Prof. Jackson, of the University of Wisconsin; T. D. Lockwood, C. E. Scribner and others gave affidavits to the contrary effect.

The Court stated in substance that it was his impression that there was no invention in the Firman patent; that he was unable to see upon what ground Judge De Haven had sustained the validity of the patent, in view of the prior state of the art, and especially in view of the Dumont English patent of 1851, and he advised counsel for complainant that, in his opinion, if the case went to the Circuit Court of Appeals, they would have great difficulty in sustaining that opinion.

He also stated that one of the decisions cited by Judge De Haven in his opinion had been discredited by the Circuit Court of Appeals of this Circuit in an opinion filed but a few days ago, and that it was very doubtful, to his mind, whether there was any invention in the Firman patent, or if there was invention, it was extremely doubtful if defendant infringed. He said, however, that he preferred to place his decision at this time broadly upon the principle that the Telephone Company at St. Louis was engaged in a public service; that the question was doubtful, and that the defendant Switchboard Company was undoubtedly solvent and would be able to pay any damages that might be recovered if the complainant should succeed in establishing the validity of the patent and the fact of infringement; and that it would, under such circumstances and also in view of the early expiration of the Firman patent, be an abuse of discretion for him to entertain the petition for an injunction, which he therefore denied.

The Kellogg Switchboard and Supply Company, to which we are indebted for these details, and which is a Chicago corporation, has, for about a year past, been constructing the switchboard for the Kinloch Telephone Company at Highland Park, Ill., where it has had from 150 to 200 men in its employ. The switchboard, whose construction was attempted to be enjoined, is being made under the patents of Milo G. Kellogg, of Chicago, and has a present capacity for 6,160 telephone lines and provides for an ultimate capacity of over 20,000 lines in one exchange. The largest telephone switchboard heretofore constructed has had a capacity for switching only about 6,000 telephone lines in one exchange.

ROCHESTER, N. Y. The Automatic Telephone Co. is expecting to get a franchise from the city under contract to have an exchange operating by July 1, 1899, with 1,000 subscribers, the flat rate being \$48 per year.

American Electro-Therapeutic Association.

The eighth annual meeting of this body is to be held at the Public Library, Buffalo, Sept. 13, 14 and 15, with headquarters at the Hotel Iroquois. A good programme and a good exhibit of apparatus are promised. Dr. W. J. Morton is to deliver a special lecture on X-ray work.

A. A. A. S. and S. P. E. E.

The meetings of the American Association for the Advancement of Science and of the Society for the Promotion of Engineering Education will take place at Boston this month, both at the Massachusetts Institute of Technology. The Association holds its meetings during the week from August 20 to 27, when a number of interesting papers on physics and electrics will be presented. The Society will meet August 18, 19 and 20, when several papers will be read by men well known in the electrical field.

MERCHANTS' ASSOCIATION OF NEW YORK has just issued at a cost of \$8,000, and is distributing by mail, 150,000 copies of a very pretty and useful booklet entitled "Summer Days and Nights in New York." The object of the book is to direct attention to the facilities of New York as a market and to its many charms as a resort with the Atlantic beaches in its front yard. The Association hopes to secure further membership among merchants, and its officers deserve much encouragement in their efforts to advance the prosperity of Greater New York.

Mr. A. J. Churchward.

The Fort Wayne Electric Corporation has been successful in securing the services of Mr. A. J. Churchward, so long connected with the Excelsior Company as electrical engineer. Mr. Churchward is generally known throughout the United States for his great success with single phase alternating motors, and rotary transformers. His latest patented device is a unique brush holder which the Government has adopted as standard. The Fort Wayne people are to be congratulated. It is understood so soon as their new factory is completed, they will enter extensively into transmission work.

MR. E. M. SMILES, formerly with Mr. Edison as an X-ray expert, has opened offices at the Townsend Building, Broadway and Twenty-fifth street. He has had a large and unusually varied experience in this field, and is on the lookout for work of special difficulty and interest.

MR. A. J. MATHESON, proprietor of the Marlboro Wholesale Grocery, Bennettville, S. C., has gone in heavily for the use of telephony as an adjunct to his business and in reaching his plantations, with a central office at Blenheim. The Matheson Telephone Co., has about 50 miles of line in use and will put up more. Its switchboard, etc., was furnished by the American Electric Telephone Co. of Chicago.

MR. CARL MODREGGER, E.E., of the firm of Siemens & Halske, Vienna, is on a visit to this country investigating American electrical apparatus, plants and methods.

MR. F. W. PECK, of Chicago, has been appointed U. S. Commissioner General for the Paris Exposition of 1900. He is establishing his headquarters at the Auditorium, Chicago, and will open offices also in New York and Paris; the assistant commissioner general taking charge probably of the New York office.

MR. THEODORE WATERS has in the August issue of the "Home Magazine" an interesting illustrated popular article descriptive of the use made in this country electrically of great water powers for transmission purposes.

MR. J. W. LIEB, JR., General Manager of the New York Edison Company, was until lately president of the Stevens Institute Alumni Association, and has now been elected alumni trustee of the institute by the Board of Trustees.

Mr. Tanner on Conventional Electrical Diagrams.

WITH regard to the present discussion of appropriate electrical diagrams, Mr. D. W. C. Tanner, of Chicago, has addressed the subjoined interesting letter to Mr. T. W. Grier, chairman of the Committee on Diagrams of the Chicago Electrical Association:

I have your favor of recent date calling my attention to an article on the subject of Conventional Electrical Diagrams which appeared in The Electrical Engineer for July 14, and in other technical journals, and in which Professor Andrew Jamieson, of London, suggests a number of modifications in the diagrams which were adopted by the Chicago Electrical Association and published by that body in pamphlet form.

When first preparing a paper on the subject, and subsequently, as chairman of the association's committee, one of the first and greatest difficulties I encountered was that of selecting diagrams which would meet the approval of a majority of users. It was impossible to please everyone. Nearly all of the modifications suggested by Professor Jamieson were carefully considered by the committee, and gave place to others which were subsequently formally adopted by the association, the reasons for such action being chiefly as follows:

Field magnet coils and other helices were represented by zig-zag lines instead of a succession of curls, because the zig-zag lines are more easily drawn, and, when associated with the conventional symbol for a commutator and brushes, or with a core, would never be mistaken for non-inductive resistances.

It seems to me that, with the association's symbol for a motor generator if it were shown as connected in circuit, less confusion of lines would result than if Professor Jamieson's form were substituted, because the two commutators are more separate and distinct, although occupying a little more space.

The usual alternate long thin and short thick lines are so universally used for a simple voltaic battery that when it is required to indicate positively a storage cell, some more striking distinction than the mere letter S must be used; hence our enclosing rectangle.

The suggestion as to the constantly driven magneto generator is, as it seems to me, a good one, and might with advantage be adopted, although the symbol shown in our pamphlet is more commonly used in this country.

It was thought, when selecting symbols for ammeters, voltmeters, wattmeters and galvanometers, that the forms adopted were desirable because they were more distinct from one another than those recommended by Professor Jamieson. There is, of course, room for a difference of opinion here.

Regarding the solenoid, I am unable to see how it can adequately be represented without showing its core; how can a solenoid do any work if there is nothing to be attracted?

If there were any diagrams for which the committee expected general approval, they were those representing a voltaic battery and a "ground;" yet it seems that the latter, at least, is the subject of objection. I can only say that the use of the association's symbol is so general that a defense of it is hardly needed.

Professor Jamieson's suggestion as to individual arc lamps seems a good one; indeed, such a symbol was among those which I recommended to the association in my paper, and it is printed in connection therewith in The Electrical Engineer for February 3, 1897. The telegraph key suggested is also a good one, and is widely used, as is the very similar one shown in the association's pamphlet. A different opinion may, however, be held as to incandescent lamp and fuse.

In conclusion I can only repeat that it is difficult to please everyone; but that with the exceptions above noted, the diagrams adopted by the Chicago Electrical Association seem to me to be fair examples of those used in the best American en-

gineering practice. It is gratifying to note the interest which has been manifested in the work of the association, and our thanks are due Professor Jamieson for some valuable hints, which may guide future work along this line.

HANDBUCH DER ELEKTRISCHEN ACCUMULATOR-EN. (Handbook of Electric Accumulators.) By Dr. Paul Schoop. Ferdinand Enke, Stuttgart, 1898; 514 pages; 6 x 9 inches; 193 illustrations; paper. Price, \$4.80.

THE literature of the electric accumulator which has thus far appeared in book form is not very extensive, and the books which are available are without exception limited in their scope. Thus we have on one hand, works devoted almost exclusively to the description of accumulators old and new, good and bad, while there are a few that have attempted to give the practical side of accumulator work, with but scant attention to the construction of the batteries themselves. Dr. Schoop's handbook is got up on an entirely different plan. His object has been to present to the reader the actual conditions existing at the present time, both as to the types of accumulators and their methods of manufacture, and as to the methods of handling them. In doing this he has not pretended to give a full description of all the accumulators thus far actually constructed, while on the other hand he has thought it advisable for his purpose to cite numerous fundamental patents bearing on accumulators, deemed worthy of mention to help furnish a clear idea of the state of the art.

The work begins with a critical discussion of the raw materials entering into the construction of storage batteries, such as lead, antimony, oxide of lead, sulphuric acid, water, etc. Dr. Schoop insists, and with a good deal of truth, that grievous sins of omission have been committed in this direction. He does not, however, content himself by the mere enumeration of the tests which the raw material ought to undergo, but in every instance gives the method of test, thus affording a safeguard for the storage battery manufacturer and user as well.

He then takes up the manufacture of the grids, showing the details, such as casting, pressing, cleaning, etc., with a special chapter on the method of carrying or holding the active material. In this we note all the principal types of grids used and proposed, the illustrations being drawn to scale, as, indeed, are all the working drawings throughout the book.

Under the chapter devoted to "active material," Dr. Schoop gives in full the mixtures employed, and the method of their preparation, including a description of the machines employed for this purpose, together with the precautions which must be taken in order to insure success in practice. To this is added a chapter on the forming of the plates, together with complete descriptions and diagrammatical representation of switchboard arrangements, etc. A short chapter is also devoted to the discussion of electrodes with porous partitions as well as the gelatinous electrolyte of silicate of soda; all these being given in detail. The methods of transporting and setting up accumulators have not been overlooked, and, indeed, this part of accumulator work is well deserving of careful attention. To this are added chapters on portable accumulators and storage battery accessories.

Under Chapter X the author discusses the capacity, efficiency and resistance of lead accumulators, and gives the results obtained by various authorities. Quite a large amount of space is devoted to an investigation carried on by the author and another, of the relative capacities, etc., of various accumulators put through actual tests. These were very carefully executed and the methods are so fully described that they may well be taken as a guide for others undertaking similar work. In the chapter devoted to the theoretical discussion of the electrochemical action which takes place in lead accumulators, the author has sought to give the most generally accepted theory on this point, as well as the special viewpoints taken by various investigators. The work closes with a chapter describing a variety of reversible galvanic combinations other than those of

lead batteries, such as the zinc accumulator, the iron accumulator, etc.

Taken as a whole, the work is the most elaborate and far-reaching of its kind which has thus far come under our notice.

Dr. Schoop has evidently made the storage battery the subject of long and accurate research, but while giving his own conclusions, the full details presented upon which these conclusions are based permit the reader to form his individual estimate. The wealth of detail and illustrations throughout the work gives it a practical character, missing, as a rule, in works which enter so deeply into the causes of things as does this of Dr. Schoop's. We can heartily recommend it to all engaged in storage battery work, whether as makers or as users.

To Change the Axis of the Earth and Freeze Out Spain.

WHAT appears to be the largest electrical installation ever contemplated and which has for its object not only the revolutionizing of the earth, but even the turning of it, has been carefully worked out by Mr. Newton Harrison, E. E., editor of the "Electrical Age," and was published in a recent number of the New York "World." In the words of Mr. Harrison, whose imaginative powers seem to be equal if not superior to those of Jules Verne: "I would girdle the earth with a giant cable. Through this I would send a current of electricity strong enough to overcome the present magnetic poles of the earth. This would give us a new north pole and a new south pole. The effect of this would be to transform the earth into a huge electromagnet of such tremendous power that it would tend to lean violently toward the sun, because the sun's chief constituent is iron."

He goes on telling us of the new positions of the continents and how Spain would have to yield or die of frost. The total cost of establishing the plant he figured out to be \$146,000,000,000 and the time required to complete the work 10 years. The cable is to consist of ten strands, each 12 inches in diameter, its length is 25,000 miles and its weight 264,000,000 tons. The current required would be 1,000,000 amperes, and the pressure 10,000,000 volts. The attractive force of the coil he figured out to be 58,000,000,000 pounds, and the power required 13,000,000,000 h. p.

The scheme seems certainly feasible, and there would not be the slightest trouble in raising the money. But Mr. Harrison wants too much time for the work.

Rapid Electric Conduit Laying.

THE marvelously quick electric railway construction work of the Metropolitan Street Railway Co. of New York within the last few years seems to have been equaled or even surpassed recently by the Knickerbocker Construction Co. in laying a mile of conduit for the Amsterdam Electric Light, Heat & Power Company of Brooklyn. The contract was awarded to the Knickerbocker Construction Co. of New York City on May 14, 1898, and it was provided that the work should be completed by June 14, 1898. The work was begun on June 1, 1898. The line of proposed work began at Bedford avenue and South Fourth street, and continued to Grand street, and from Berry to Union avenue on the south side of Grand. The specifications required 3 inches of concrete to be placed on bottom, top and sides of the McRoy conduits. Concrete was composed of five barrels 1-inch trap rock and two barrels sharp sand and one barrel Portland cement. The plans showed the depth of excavation to be 34 inches, but it was necessary for almost the entire distance to excavate to a depth of 4 and 5 feet to avoid the pipe of other companies. In many instances it was almost an impossibility to find room for the manholes, which were placed at all street corners. The interests of the company were looked after by Mr. C. W. LeCault, the company's superintendent. Mr. James Pilkington, president of the Knickerbocker Construction Co., personally superintended the construction. Mr. John Edgington was the city inspector. Mr. Pilkington had an average of forty-eight laborers and two foremen at work, and completed

the entire work in fourteen working days, repaved the street and removed all waste material. The surplus material was carted away as fast as it was taken from the trenches, and for that reason storekeepers and pedestrians were less annoyed than on other work of like character. The streets were paved as fast as the conduits were placed in the trenches, refilled and rammed.

Flag Raising at the Works of the Fort Wayne Electric Corporation.

PATRIOTISM and good feeling must have run high on the evening of July 16, when the employes of the Fort Wayne Electric Corporation of Fort Wayne, Ind., raised the largest flag and dedicated the largest pole and equipment in the State of Indiana, at the factory of the corporation. Long before the opening of the program a crowd of 15,000 people were assembled about the works. The electrical display was a grand one. Searchlights illuminated all the nooks in the neighborhood and by the rays thrown over the crowd its size could be seen. Connecting the office and factory buildings was a large arch made of incandescent lamps. The words "Fort Wayne" were worked out in large letters. Up on the north side of the main building was a small light and under it hung the effigy of a Spaniard.

Mr. E. A. Barnes, acting superintendent of the works, made the presentation speech in the name of the employes, and Mr. J. J. Wood, the electrician and general superintendent, accepted the flag for the corporation, in the absence of Mr. R. T. McDonald. Mr. Barnes, in presenting the emblem, made many remarks flattering to the company and its officers, and very hearty was the response of Mr. Wood. After a few appropriate remarks by Mr. E. H. Worden, Judge R. S. Taylor delivered a stirring patriotic address, in the course of which he said: "The time has come for a new development. The employes of the Fort Wayne Electric Corporation want to sell dynamos around the world. Where the flag goes ships will go, and where the ships go there will go Fort Wayne dynamos. It means larger markets, more work, more prosperity and more happiness if we learn how to utilize it."

The flag equipment, which is now the proud possession of the corporation, is erected on the northwest corner of the factory where the walls are of sufficient strength to withstand the strain. The pole, eagle and flag in position have an aggregate weight of 3,500 pounds. The pole is clamped to the corner of the building with heavy wrought iron clamps, and its construction is unique, the centre being composed of wrought iron pipe varying from 4½ inches in diameter at the base to 1 5-16 inches in diameter at the top. This pipe not only acts as the backbone of the pole, but at its lower end is connected to earth so as to form a lightning rod. It also has running through its center the copper conductors which furnish current to the lights suspended from the eagle's beak.

The golden eagle which surmounts the pole is also unique in arrangement, standing as it does on a 12-inch sphere and holding in its beak a 6-inch golden ball from which project the national colors composed of three red, white and blue 50-candle power electric lamps. The eagle and its equipment weighs 50 pounds, stands 6 feet high, has a spread of 6 feet 6 inches from tip to tip, and stands 150 feet above the sidewalk.

The flag is 54 feet 6 inches long and 32 feet 6 inches wide. The stripes are each 2 feet 6 inches wide, while the total weight of bunting used in its construction is 60 pounds.

Niagara Electrical Engineers in the War.

Captain Alfred E. Hunt, president of the Pittsburg Reduction Company, is a member of Battery B of Pennsylvania, which has been ordered to Porto Rico. Electrical and engineering circles at Niagara Falls are centered in their interest in the doings of the 1st Regiment Volunteer Engineers, to which orders have been given to leave for Porto Rico on Wednesday, August 3. In this regiment are several well known electricians who enlisted in the 42d Separate Company at Niagara Falls and went from there to Camp Black, the company being now at Camp Alger, and known as Company E of the 3d Provisional Regiment. Among the men who thus started for the front were J. R. Haskins, Francis M. Blacklock and

William Hopkins. Soon after reaching Camp Black they were transferred to Camp Townsend, where Messrs. Haskins and Hopkins received commissions as Lieutenants and Mr. Blacklock was made a Sergeant. Lieutenant Haskins was formerly with the Niagara Falls Power Company, and Lieutenant Hopkins with the Carborundum Company. Sergt. Blacklock was also with the Niagara Falls Power Company. James Elliott Hewes is also a member of the 1st Regiment Volunteer Engineers, and ranks as Lieutenant. He is from the Falls, where he was connected with the Carbide Company. Still another Niagara Falls man is Archibald R. Livingstone, who holds a Lieutenant's commission. He was connected with the wheel-pit extension work. Corp. Edwin J. Murray, of this regiment, is a son of Sheldon T. Murray, who is the superintendent of the Niagara Falls Water Works Company, one of the allied companies of the Niagara Falls Power Company. Mr. Murray was on the engineering force of the Cataract Construction Company at the Falls.

Sixty-Foot Rails for B. and O.

The receivers of the Baltimore & Ohio Railroad have purchased forty miles of 85-pound sixty-foot steel rails, and will experiment with them on the Pittsburg Division, and in the Baltimore tunnel. These rails were originally bought for the Columbia & Maryland Electric Railroad, which was designed to parallel the Baltimore & Ohio Railroad between Baltimore and Washington, and to become an important factor in business between those points. The project failed, and the material which was purchased has been sold.

McGill University.

THE announcement of the Faculty of Applied Science of McGill University for the session 1898-99 has been received and gives a detailed description of the various courses taught in this well known university. The electrical engineering course, for which at the present time the Faculty is endeavoring to fill the chair of the McDonald Professorship of Electrical Engineering, appears to be a thoroughly practical one, in which the most careful attention is given to strictly technical details. The University is supplied with well equipped laboratories and shops, which have recently been enlarged with the aid of generous donations; and the coming year will certainly be one of prosperity for this modern institution.

Peace Prospects.

This country appears to be now within measurable distance of peace with Spain, and there is an immediate better feeling. The country comes out of war with enhanced prestige in many ways, and besides having set Cuba free, finds a hearty welcome as ruler in Porto Rico, and in such parts of the Far East as it may be found expedient to retain. There is improvement in the iron and steel industry, the outlook for very large crops is bright, and the fall trade opens up well, especially out West. Bank clearings were 28 per cent. larger than in the week of 1896, while failures fell off from 259 to 189. Gold imports are beginning, a sign of our unusually small imports of goods and our enormous trade balance.

During the past week, 13,178 shares of Western Union were sold, from 92½ up to 93¾. Of General Electric, 6,442 shares were sold, around 39½. In Boston, Am. Bell Telephone closed the week at 278½, the rise being attributed to the sustaining of the Carty "bridging bell" patent. N. Y. Edison sold at 131.

TRADE NOTES AND NOVELTIES

The Franklin Electric Supply House, Philadelphia.

Mr. H. P. Feister.

The importance of Philadelphia as one of the leading centres of electrical trade in this country bids fair to be considerably enhanced by the establishment of the enterprise which is to be known as the Franklin Electric Supply House. In resources, facilities and lines represented it will be remarkably strong, and the spirit which has carried its proprietor to pronounced success in other fields may be expected to make itself felt in this new one also. Mr. H. P. Feister, who has organized the enterprise as its proprietor is well known in the machinery world and has long been engaged in the production and sale of printing presses embodying his own inventions and improvements. He early saw the adaptability of the electric motor to such work as operating presses, and has installed large numbers in connection with his own machines. Becoming thus intimately acquainted with electrical apparatus and possibilities, and being further a man of great energy and resource, he has determined to develop his ideas also along electrical lines, with the aid of a first class staff and starting out with popular and standard lines of supplies. Special attention will be paid to electric lighting, power work and telephony, but no branch of the now great electrical supply industry will be neglected. Among the lines taken up by the Franklin warehouse as wholesalers and jobbers are the following: Commercial Electric Co., dynamos and motors; Highland Electro Chemical Mfg. Co., Highland soldering paste; W. S. Hill Electric Co., switches and switchboards; Ohio Electric Specialty Mfg. Co., automatic motor starters, commutator lubricant, perfection brushes, woven wire brushes and leaf copper brushes; Riley Bros., magic lanterns,

THE FRANKLIN ELECTRIC SUPPLY HOUSE, PHILADELPHIA.

stereopticons and kineoptoscopes; McNamara Bros., slate and marble for all purposes; Schmidt & Bruckner, 20th Century telephones; Prismatic Electric Sign Co., prismatic electric signs; D. L. Bates & Bro., fan motors, etc.; Oshkosh Logging Tool Co., electrical construction tools; John Rauscher, push buttons, the Franklin incandescent lamp, American burners. Chapman voltage regulator and Crefeld wires and cables. It will be seen that this is a very comprehensive and representative list. Mr. Feister's staff will be an excellent one, including

a number of well known electrical men. The warehouse itself is a fine commodious building, located at 506 and 508 North street, now called Cuthbert street, opposite Christ Churchyard, at Fifth and Arch streets, a bare block from the tomb of the great electrician whose name it bears. The proprietor and salesmen will be glad to receive the calls there of old friends and new, and will either send representatives to parties desiring quotations or will furnish prices, etc., by mail. They believe they can offer inducements that it will not be possible to resist in the way of advantageous trading.

Stamped Metal and Cornice Work of J. H. Eller & Co., Canton, Ohio.

It is seldom that art and utility are found so harmoniously combined, in the products of a manufacturing establishment, as in the articles produced from the works of this company. Stamped metal work is the broad term under which the output of this establishment is comprised, but it conveys only a faint idea of the variety of uses and designs to which sheet steel lends itself, when manipulated by such genius and skill as characterizes the management of this company. Skilled artists are employed for designing and the company can supply anything in this line of work, for there is no limit to the special designs that can be made from a combination of classic forms by the substitution of different fillers and moldings and a proper arrangement of different sets of panels. The designs are first all modeled in clay and from these plaster casts are made which are preserved and used as patterns. From these patterns zinc or

ORNAMENTAL METAL WORK, MANUFACTURED BY ELLER & CO., CANTON, OHIO.

steel dies are cast. Zinc is most commonly used and the dies are made very thick. The stamping is done in drop hammers, one of the dies being placed on the anvil and the other in the face of the drop. Each panel receives three or four blows and the sheets are passed in very rapidly one after another. After being stamped, panels are retrimmed either on band saws or shears to insure accurate and close-fitting joints when in place. For stamping panels and metal ornaments for cornice work, five drop hammers are employed with an accompaniment of saws and trimming tools. These are all located in the basement of the building and are operated by electric power.

Cornices are made either of galvanized sheet plate or of copper, the former metal being mostly employed. The designs in cornices are about as numerous as for ceiling panels, and call for artistic skill of a high order. One would need to study the handsome catalogue sent out by this firm in order to form any sort of an idea of the range and character of this work. The output includes not only spun metal balls, but also balusters, urns and lamp reflectors. Besides these forms which are allied to the galvanized cornice, there are letters, and moldings for gable ornaments; also finials and weathervanes in great variety,

besides ventilators, skylight frames, ornamental crestings, ridges and chimney caps.

Roofing and Sheeting.—Both painted and galvanized sheets are employed for this purpose. No galvanizing is done by the company, however, but the black sheets are painted for roof work, and for this purpose a number of paint grinding machines are provided, in which the iron oxide or metallic base is ground in pure linseed oil and is applied to the plates by means of rollers, one of which dips into a vat of paint, and through which the sheets are passed rapidly and then placed on racks for dry-

METAL CEILING MADE BY ELLER & CO., CANTON, OHIO.

ing. For roll roofing, the sheets after being painted are united in strips by means of a flexible double lock cross-seam, a specialty with this firm. For this purpose a special machine is provided on which the ends of the sheets are double folded and are then locked by being slid in place sideways. The sheets are then rolled into 50-foot lengths, and in the process of rolling, which is done by hand power, as each cross-seam comes under a press or groover in passing on the roll, the operator by means of a foot lever causes the die to descend, which presses the cross-seam flat and tight. The rolls of material are then wrapped in paper, and securely tied with wire for shipment. Roofing tools are provided by the company either for applying their pressed standing seam anchor-cap or lock-seam roofing. The company also make crimped edge and three crimped sheets of both painted and galvanized steel. The same material is also corrugated to different depths for roofing, siding and awnings, and this is done in presses instead of on rolls, as is usually the case. By the stamping process the metal is said to be left more uniform and better for making laps. The corrugating press is a large machine capable of crimping plates 10 feet in length and the dies are actuated by means of a series of five toggle joints and is run by an electric motor, as are several other of the finishing and stamping machines. The curved corrugated sheets are arched lengthways to any radius by passing them through a set of rolls which are beaded to fit the corrugation. The material is also pressed to imitate ordinary board siding, pressed brick, or rock-faced brick and stone, either in blocks or continuous and cluster tiles and shingles and cluster shingle siding. The claims for siding of this kind are that it is fireproof, ornamental, and can be put up for a small part of the cost of brick or stone walls.

A large part of the output of the works consists of galvanized steel eave troughs and conductor pipes, the latter being either corrugated, round or square. Suitable hangers are also made of two patterns, one of stamped metal and the other of galvanized wire, twisted. This department is equipped with a full line of machinery for shearing and bending, beading and corrugating. The eave troughs are made in 10-foot lengths without seams and in five sizes, ranging from 13½ inches up to 8 inches, and are usually made of No. 28 gauge metal. The troughs are made with single or double bead, but are usually single and with an improved slip joint that requires no soldering and is not affected by expansion. The conductors are also made in 10-foot

lengths without cross-seams and are corrugated after being rolled round, by placing the pipe over a mandrel having grooves throughout the whole length when the corrugations are formed by means of small wheels which register with corrugations in the mandrel and being mounted in a sliding head are actuated back and forth by means of a sprocket chain that runs over reversing pulleys at each end. These are operated rapidly and have a capacity for corrugating several thousand feet of pipe per day. The work in this department includes conductor strainers and heads; also "Safety" lock-lever cut-offs. Elbows and shoes are purchased from other parties.

Oil Cans.—In this department two types of oil cans are manufactured, one of glass known as the "Leader," the other of galvanized metal and known as the "Canton." The former is made in one gallon size only and consists of a glass cup protected by an ornamental tinned wire jacket with bands at top and bottom. The "Canton" is made in one and two gallon sizes with spouts, three and five gallon sizes, either with a faucet or spout. A large department on the third floor is devoted to this branch of the business, and is provided with numerous soldering furnaces in which the fuel is gasolene. The cans are all tested for leakage before shipment by means of air pressure, the can being immersed in a tank of water so that the slightest leak is detected by the escaping bubbles.

The works occupy a three-story frame building 150 x 200 feet, located on Tuscaras street and the Fort Wayne Railway. The office and draughting room occupy part of the first and second floors, fronting on East Fifth street. Shipping facilities are excellent and the product goes to all regions. This company makes a specialty of supplying cornice, skylights, metal ceiling and ornamental work for large buildings, and they have recently secured several large contracts for material of that kind. Mr. J. H. Eller is sole proprietor of the business.

The Williams Electric Co., Cleveland, O.

THIS is comparatively a new company, but enters the field with a manager who has had long experience in the manufacture of telephone supplies, especially magneto bells. Its principal product at present is confined to magneto bells and telephone receivers. These specialties have many points to recommend them, being developed in every direction beyond the ordinary devices that bear the same name. Some of the special features of the bells are shown in the accompanying illustration.

Fig. 1 is an illustration of the generator, showing a full front view. The magnets are held on to the pole-pieces by brass

FIG. 1—WILLIAMS MAGNETO GENERATOR.

bolts, and the arrangement is such, that there is no space between the central and the outer magnets, so as to utilize all of the space on the pole-pieces that is radially adjacent to the armature. There is also a very perfect and ingenious method of taking the magnetism from the permanent magnets, and distrib-

uting it uniformly around the cylindrical surface of the pole-pieces, by means of contact plates that are illustrated in Fig. 2.

Each contact plate has two ears turned inwardly to hold it in position on the pole-piece, and has, also, four ears turned outwardly to hold the permanent magnets rigidly in their proper place on the generator.

Three portions of this contact plate are left flat or straight, so as to make a good contact surface on the permanent magnets, and two portions are formed so as to make curves coincident with the outside curvature of the pole-pieces. This arrangement not only gives perfect contact between the permanent magnets and pole-pieces, but also takes the magnetism from the permanent magnets, at or about a horizontal line bisecting the armature circle. The advantage thus gained is, that instead of short-circuiting the permanent magnets, by allowing

FIG. 2—GEAR OF WILLIAMS MAGNETO.

the pole-pieces to make contact at a higher point, a considerable longer length of permanent magnetism is utilized to drive the magnetism through the armature, instead of being given up entirely to the one purpose of making contacts. In this way a better contact is obtained than in the old way, and at the same time a greater effective length of permanent magnets.

The end plates which hold the shaft bearings, are punched from heavy brass, and have riveted into them very long brass bearings, which is a very important feature toward making the machine run quietly for a long period of time. These end plates are practically self-centering, so that the armature can be shifted and held centrally in the curvature of the pole-pieces, so as to prevent the armature wings from striking. This feature is important when it comes to making repairs on the generator, for one is enabled to take this machine apart and repair the winding, and reassemble it without the use of any special tools or appliances, and with but little trouble.

This machine is equipped with a very reliable clutch form of automatic shunt, or cut-out, which, by reason of its simplicity of construction, is not liable to get out of order. The driving gear is of novel construction, and is placed on the left-hand side of the generator so as to avoid unequal wear on the gear bearings, caused by turning the crank. This feature entirely obviates the disagreeable noise caused by the unequal wear of the gear bearings, due to operating the crank, and the proper centre distance between the gear shafts is maintained indefinitely.

The gear is made from a brass punching, which is radially corrugated, the object of which is to provide a driving gear that will distribute its tooth surface over the tooth surface of the pinion in an absolutely uniform manner. This gear—paradoxical though it may seem—will, it is said, not only last longer, but will run quieter during its life, than will a wide face cast cut gear, for the following reasons: Owing to the exact equality of the tooth surface of both the gear and pinion, the wear on each of them will be precisely the same, in spite of the difference in their diametrical sizes, as will be seen at a glance, from the illustration. This novel feature produces an exactly uniform rate of wear on all of the surface of all the teeth on both the gear and pinion. The effect of wearing at the same rate will maintain to a greater extent the proper curves of the teeth, of both the generator and pinion, causing them to roll one upon the other, instead of sliding and grating, as would be the case with the wide-faced gear, whose companion pinion wears more rapidly than the gear.

The pinion is attached to the armature shaft, by means of a key and a machine screw, and can be instantly taken off and replaced without having to be driven off or on, as is the case of many forms of generators heretofore constructed. This little feature is of great convenience when repairs are necessary. The object of the designers of this instrument has been to construct a magneto bell that would last indefinitely, with but few repairs, and so constructed that all necessary repairs can be made with the slightest possible loss of time or cost of material.

The resulting wave of current of this generator, due to the peculiar construction of the pole-pieces, approaches very closely the sinusoidal form, and is very useful in transmitting signals over long, leaky lines, having a high coefficient of self-induction or static capacity, thus making this instrument ideal for toll line work.

The ringer, as will be seen from Fig. 3, is a decidedly new departure. It has but a single core, which is parallel with the vibrating armature. The core head or end pieces are formed up of Swedish iron, and are swaged on to the core under an enormous pressure, which practically welds the end pieces to the core, forming a very perfect magnetic joint. There are no screws used to secure the core; therefore, no possibility of deterioration of the electromagnetic circuit due to effect of rusty joints and loose screws.

The permanent magnet of the ringer is of the consequent pole type, which has the armature suspended from the central and consequent pole. It strikes a very hard and stiff blow to the gongs, and in perfect unison with the generator pulsations, irrespective of the speed of the generator. This is a very valuable feature when it comes to toll line signaling, where sharp, clear and distinct signals are almost an absolute necessity. The core being situated longitudinally between the end poles of the permanent magnet, is constantly subjected to a magnetic stress, which accounts for the delicate responsiveness of this ringer to extremely weak currents, on the same well known principle under which an ordinary telephone receiver operates, as there is already a magnetic field existing in the core of the ringer, and it is a well known fact, in electro dynamics, that it requires a much smaller current to produce a given effect on an existing field of force, than would be necessary to create the field of force, in addition to the effect. In other words, in operating this ringer, it is not necessary to swing the core, and with it the remainder of the electromagnetic circuit through so long a cycle as is necessary in all previous forms of ringers.

The general appearance of the complete bell, is as in Fig. 4, which shows the long lever gravity switch hook, with Craig sil-

FIG. 3.—THE RINGER.

ver contact pieces firmly attached to a hard rubber block, which, together with the hook, is mounted in the bell box in such a way, as to make the switch hook entirely self-contained, the advantage of which is obvious. The cabinet work is wired throughout with tinned copper wire, which rests between tinned spring washers, secured by screws entering the binding posts, thus forming spring contacts—all other contacts are soldered. This valuable feature will save much trouble due to loose contacts.

The receiver cord binding posts, which are located on the lower left-hand corner of the base of the instrument, are very unique in design, and are formed in such a way as to form a lock for the receiver cord tip, that will hold it like a vise, and at

the same time hold it in position with a firm but spring pressure, which will prevent it from working loose and dropping out of the binding post.

In the design of this bell, every point in the construction of magneto bells has been carefully considered, and every defect developed in existing forms, has been studiously avoided and ingeniously remedied. These machines are wound with the best quality of insulated copper wire, to ring through any specified resistance, from the standard of 10,000 ohms up to 150,000 ohms.

This company are also designing a bridging bell system that they will shortly have ready for the market, which, it is claimed, will be clear from all possibility of infringement of the Carty patent, being at the same time fully as efficient.

The works occupy the third and fourth floors of the Kennard Building, No. 80 Seneca street, overlooking Lake Erie. The rooms are well lighted and the floor space aggregates 10,000 square feet. The power is supplied from the building plant, and the tool equipment in the metal working and assembling departments is very complete and of modern design. Among the special machines, may be noted an automatic gear cutter on which the teeth of the gears and pinions are cut, several turret-headed lathes and a number of die-making tools. In the winding de-

FIG. 4.—COMPLETE WILLIAMS MAGNETO BELL.

partment are four specially designed machines for winding the spools and armatures, each of which is provided with an automatic device for registering the number of convolutions. A great number and variety of dies, all of special design, are provided for stamping out the various parts that are made from sheet metal, and these include a large proportion of the material required in the structure of the apparatus, and there are but few parts that require detailed hand work. For the making of the magnets a large power shear is provided on which the bars, which are $\frac{3}{8} \times 1$ inch, are cut into 13-inch lengths, and an open hearth double-deck brick furnace for heating the bars preparatory to bending, and this is done on a large bending machine on which either the horseshoe or the double arch magnets are bent to proper shape. These operations are followed by the polishing and buffing processes which prepare the bars for receiving the nickel plate finish, and for which purpose a very complete nickel-plating plant is being installed. One of the most interesting processes in manufacturing the bells is that of magnetizing the bars after they are bent, and for this purpose a constant potential generator is provided, from the current of which a powerful helix is energized with sufficient magnetizing power, it is said, to lift a ton. Across the core of this the bars are drawn several times when they are permanently and strongly magnetized so that the three, constituting a field of each bell generator, are able to lift magnetically 20 pounds. Special care is exercised in selecting the metal designed for the field magnets and it is of such a character that its magnetism has never

been known to deteriorate and the nickel-plating does not crack.

The arrangement of the stock room is an illustration of the system that prevails throughout the shop. Here open boxes are provided for each particular part that enters into the construction of the bells or receivers and these are so arranged on stair shelves that any piece at any time may be readily found and the contents of each can be readily inspected and replenished before the stock of any particular box is exhausted. In full running order the works will employ 175 hands and the capacity will be equal to an output of 250 magneto bells per day.

The organization of the company includes the president, J. A. Williams, who was formerly of the Williams, Abbott Company, of Cleveland; the vice-president, Mr. F. J. A. Keller, and B. S. Chamberlin, secretary and treasurer, who was formerly with one of the prominent street railway companies of the city.

W. H. Sills Mica Co.

The W. H. Sills Mica Co., of Michigan avenue, Chicago, have recently put on the market a new line of electrical insulation known as "Micabeston," which has stood the highest tests and is pronounced by authorities "perfect insulation." The line includes Micabeston plates for rings and other moulded insulation which may be made into any form by heating; Micabeston plates for segments for commutator uses, which will not ooze and is so perfectly made that commutators insulated with Micabeston can be put together perfectly without baking, a trifling heat being required to soften the ring so that the commutator may be thoroughly tightened. In addition to flexible Micabeston, oiled cloth and paper, they make all shapes and styles of insulation and have experienced a remarkable trade for the time established. They are now employing 50 people and are adding hands each week. They will open a New York branch before the end of the year, and contemplate sending a representative to England and Germany soon after the new year, with a view to opening a plant to supply European trade.

An Immense Walker Order for France.

An unusually large foreign order for electrical apparatus has been received by the Walker Company, of Cleveland. The order came from the Exploitation des Procédés Electriques Walker, the Paris agency of the Walker Company, and was for 500 complete street railway equipments, comprising 1,000 25-horse-power motors, 1,000 controllers, and 500 trolleys. The apparatus will be the standard make of the Walker Company and will be distributed through cities in Italy, France, and Germany. An officer of the company stated that the order would be equal to equipping all but fifty of the motor cars in use in Cleveland at the present time. The money represented is in the neighborhood of \$500,000. The order is to be filled in fifteen months. Apparatus manufactured by the Walker Company is now in use in Alexandria, Egypt, in Paris, and in a number of smaller places in France.

The K. & W. Company's Remarkable Fan Motor Offer.

These are certainly days when no one who has access to the electric current will hesitate about installing in office, household or factory an electric fan motor, especially when it can be procured for an insignificant sum of money. Recognizing this fact, the K. & W. Company, of Pittsfield, Mass., are placing on the market a large number of efficient and handsome alternating current motors which they have bought from a reliable firm who have discontinued the manufacture of fan motors. The balance of the stock which was purchased by the K. & W. Company is being offered by them at prices below cost of manufacture. The motors have been on the market for seven years, and thousands of them have been sold and are running to-day. They are built for 45-58 volt alternating circuits of 16,000 alternations and are sold at the following remarkable prices: \$5 for the 9-inch fans, and \$7.50 for 14-inch fans.

This offer should appeal strongly to central station managers, who can sell the motors direct to their regular lighting customers. They can either dispose of them at a profit, or at cost, or present them free to some of their best customers or to those whom they desire to secure as customers.

Every motor running will increase the day load. They can buy a few of these motors, fit them with cord and attachment plug and leave them at the houses of prospective customers some hot day, and most of them will not permit of their removal. A motor should be set on the sideboard in their dining room and the breeze turned on the table during dinner hour, and they may then fully appreciate what a luxury it is.

The stock of these motors is very limited, and it is simply a case of "First come, first served." The company is prepared to send a motor on trial to responsible parties.

The Beacon Incandescent Lamps.

FOR a number of years it has been the endeavor of lamp manufacturers to construct an incandescent lamp, which, besides giving its rated candle power at the beginning and having a long life will retain this initial candle power for the largest possible number of hours. It appears from numerous tests made by the company and consumers, that the Beacon Lamp Co., of New Brunswick, N. J., have succeeded in producing such a lamp which they have been supplying to the trade in large quantities. The Beacon lamp is claimed to retain its initial candle power for over 300 hours, and anyone who has watched the disastrous effect on the customer's eyes as well as the risk of losing customers on account of inefficient lamps appreciates the value of lamps which have a guarantee of an average maintenance of the initial candle power for so long a time. The company are prepared to send lamps to anyone desirous of making their own tests, free of expense, so that they may judge for themselves how the Beacon lamp compares with other makes. It is claimed that careful photometric and electrical measurements have shown that after 100 to 300 hours the lamp gives more light, uses less current, blackens less and has as long life as any other lamp. The standard efficiency guaranteed by the company is 3.5 watts per candle, but lamps are made from 2.75 watts upward. The company will stand by its guarantee, which they have never failed to fulfil.

Sales of "Gravity" Motor Controllers.

Mr. G. A. Nisbet, general manager of the Electrical Appliance Co., 27 Thames street, New York, reports very satisfactory sales of their new gravity motor controllers. Their device is also finding quite a sale in New England, L. A. Chase & Co., Boston, being the Eastern representatives. In order to fill their increasing trade Mr. Nisbet has just purchased an entire carload of slate which is used in the manufacture of these goods.

American Impulse Wheel Company's Water Wheels.

The American Impulse Wheel Company of New York states that it is making steady headway with its improved water wheel, which is attracting considerable attention in this and foreign countries. The company reports that it has the most satisfactory commendations in every instance, and finds business increasing rapidly. Besides wheels shipped to various parts of the United States and reported giving most favorable results, the company has wheels installed in Japan, France, Sweden and Scotland. For contemplated large power and transmission plants in Utah, Canada, Montana and Minnesota, these wheels are being given serious consideration; and the company confidently expects the adoption in several instances. The Columbus, Ohio, plant, which this company is building will be a novel one, and will be more particularly described in these pages on completion. The company informs us that it has all the advantages embodied in its water wheel of the best heretofore in the market with added improvements as the result of the latest scientific knowledge and test. It claims to spare no pains to perfect mechanical design and construction, together with the highest efficiency, and gives special attention to regulation. Mr. Thorburn Reid is consulting engineer of the company.

LOUISVILLE, KY. A fire in the building occupied by Jas. Clark, Jr., & Co., manufacturers and dealers in electrical supplies on West Main street, resulted in a loss of \$20,000. It is said to have been due to the explosion of a barrel of insulating compound.

Wm. J. Murdock & Co.

This company, located at 160 Congress street, Boston, Mass., are circulating a small leaflet explaining their well-known telephone receiver. It is a strictly high-grade instrument of the pony type, has two poles, a hard rubber case, plate binding posts and weighs 12 ounces. The magnets, which are made of the best steel, are supported near the diaphragm, so that the change in temperature does not affect the adjustment. The cost of this instrument is \$2. The company will be pleased to answer any further inquiries about this instrument.

Emerson Electric Co.

This company is located at 714-718 St. Charles street, St. Louis, Mo., and has recently acquired control of a large number of alternating current cigar lighters, which they offer, in order to close them out, at \$4.75 each. They believe it to be a good operative article, as large numbers of them have been in use for some years. As soon as this lot is disposed of the company will manufacture this appliance and market it under the same guarantee covering all articles now made by them.

Harrison Bros. & Co., Inc.

A very complete and interesting catalogue and price list has recently been issued by the well-known firm, Harrison Bros. & Co., Inc., Philadelphia, Pa. This house, which was founded in 1793 by John Harrison, now has a factory covering an area of thirty-five acres, over two-thirds of which is occupied by sixty buildings of the most improved construction. Seven thousand tons of white lead is produced annually, and their other products include colors for coach, car and house painters, ready-mixed paint, paper makers supplies, chemicals, etc. It might be mentioned that the power plant of this enormous concern has a capacity of over 3,300 h. p., and they own one and one-third miles of private siding connecting with the prominent railroad lines. The catalogue is claimed to be the most complete paint pamphlet ever sent out to the trade, and contains complete information of the following products: White lead, red lead, litharge, zinc whites, "Harrison" oil colors, graining colors, brick paints, artists', decorators', and sign-writers' tube colors, fresco and waters colors, ready-mixed paints, stains, fillers, varnishes, japans, dry colors, acid and chemicals, a complete index and numerous illustrations.

John A. Roebling's Sons Co.'s Souvenir Catalogue.

There is, perhaps, no name which is more closely identified with industrial progress in this country than that of John A. Roebling's Sons Co., of Trenton, N. J., not alone because they are said to be the largest manufacturers of wires for electrical purposes, but also on account of the great miscellaneous enterprises undertaken and successfully completed by this company for a large number of years. It was half a century ago when J. A. Roebling transferred his wire plant and business from Pennsylvania to Trenton, and he was the first to engage in the wire making business in America. The present plant at Trenton covers more than twenty-two acres of ground, on which have been erected thirty-six large buildings. A force of 2,500 operators is employed and the material handled in a year aggregates in the neighborhood of 150,000 tons. Steam engines ranging from 2,000 h. p. down, drive the machinery, and in the boiler house 6,000 h. p. is developed. The electric lighting station supplies current for 200 arc lamps and 2,000 incandescent lamps, through copper conductors which weigh altogether 20,000 pounds. It would take pages to describe the wonderful growth of this remarkable company, and we can do no better in this short notice than to extend to its officers our sincere congratulations on its jubilee. Their souvenir catalogue deserves special mention, as it is certainly a remarkable production, and well worthy of the splendid record held by the company. It

contains, first of all, a complete history of the concern, and an elaborate description of all the processes employed by them. Then follow in order the details of construction of various bridges built by them, such as the Niagara Suspension Bridge, the Allegheny Bridge, the Ohio Bridge, the New York and Brooklyn Bridge, and various other suspension bridges. Following this are chapters on logging with wire rope, installations of cableways in various countries and numerous mines, all of them being accompanied by full-page illustrations. Then follow chapters on underground haulage by wire rope, inclined planes, power transmission by wire rope, street railway cables and the Roebling system of fireproof construction, and chapters on wire rope as well as illustrations and price lists of the various kinds of wire manufactured by the company. Then follow in order steel cables, cable and wire terminals and hoisting machines. The remaining portion of the catalogue is devoted to a thorough description of wires and cables for electrical purposes, such as copper and iron wire, magnet wire, lead encased cables, telegraph, telephone and submarine cables, bi-metallic copper wire, silicon-bronze wire for trolley purposes, their well-known Climax resistance wire, the Columbia rail bond, and a large number of valuable and thoroughly revised wire tables. All this represents a great deal of labor and offers by far the best information on the subject of wire rope and electrical wires from the standpoint of the consumer. The book is handsomely bound, is well printed, and has, as a frontispiece, a portrait of John A. Roebling, the founder of this remarkably successful company.

ADVERTISERS' HINTS

THE AMERICAN ENGINE CO., Bound Brook, N. J., say that so perfect is the automatic regulation of their direct connected generating sets, that it simply requires the pressing of a button (opening the throttle) and the machine does the rest.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, Ill., pride themselves on carrying the largest and best assorted stock of line material in the West.

THE BIBBER-WHITE CO., 49 Federal street, Boston, Mass., call attention to the "Victor" and "New Era" gas lighters.

THE STOREY MOTOR AND TOOL CO., of Philadelphia, are now located at 464 So. Broad street, Trenton, N. J.

J. H. ELLER & CO., 100 East Fifth street, Canton, O., advertise stamped metal ceilings, galvanized cornice, ornamental crestings, galvanized iron skylights and steel roofings, as well as other building materials. They publish a catalogue which may easily be obtained.

THE WESTERN ELECTRIC CO., Chicago and New York, advertise the Lakon transformer and electrical apparatus and supplies.

BEACON LAMP CO., New Brunswick, N. J., guarantee an average maintenance of initial candle power for over 300 hours at standard efficiency on the lamps made by them since the first of the year.

WESTERN NOTES

THE ELECTRIC APPLIANCE CO. have just issued a very neat circular of electrical house goods specialties for which they are general Western agents, giving particular attention to the Noxall annunciator, showing in detail the construction and operation of the machine, etc. The Electric Appliance Company will be pleased to send a copy of this special circular and price list to any of the trade who have not received the same.

CENTRAL ELECTRIC CO. In addition to carrying a large and well assorted stock of the celebrated Loricated conduit for interior wiring, the Central Electric Company, of Chicago, announce that they have full and complete lines of all sizes of circular loom conduit and plain brass and iron armored interior conduit and all fittings.

NILES & SCOTT CO., Laporte, Ind., are ordering another Thomson electric welder. The one they now have cannot keep up with its work, although it welded 112,000 wheels last year.

KOKOMO, IND. The Citizens' Light and Power Co., C. L. Harvey, manager, is in need of a good arc lamp man, who can trim and adjust.

ST. LOUIS, MO., Western Electrical Supply Co. proposes to increase its capital stock from \$25,000 to \$50,000.

MR. MARTIN J. INSULL has severed his connection with the firm of Sargent & Lundy, and has now opened an office at 1013 Monadnock Block, Chicago, where he will continue as a manufacturers' agent, handling dynamos, motors, incandescent lamps and other appliances.

MR. N. S. PARKER. The Fort Wayne Lamp Co., of Cleveland, O., notify us that N. S. Parker, traveling through the West, representing himself as an agent for the company, is not a representative of theirs at all.

NEW ENGLAND NOTES

FALL RIVER, MASS. The Fall River Bleachery, at Fall River, Mass., have placed the contract for their new mill with the Berlin Iron Bridge Company, of East Berlin, Conn. The building is 65 ft. wide and 200 ft. long with side walls of stone, the supporting framework being made of steel.

The Electrical Engineer.

Vol. XXVI.

AUGUST 11, 1898.

No. 536.

Electrolytical Processes for the Extraction, Separation and Refining of Metals—The Tommasi Process.

BY D. TOMMASI.

IN the electrolytic treatment of metallic compounds, more energy than is required for the operation itself has been wasted for the simple reason that in the electrolytic apparatuses ordinarily used, all attempts to diminish the internal resistance and reactions of the bath and to suppress polarization have failed.

The electrical resistance is due:

(1) To the distance the electrodes are kept apart, and this is

FIG. 1.—GENERAL VIEW OF TOMMASI ELECTROLYSER.

considerable particularly in the case of the refining of certain metals, which instead of becoming deposited compactly, are deposited in a crystalline state, as in the case of zinc, or in a spongy form as in the case of lead, and would lead to short circuitings if the anodes and cathodes were not kept sufficiently far apart.

(2) To the lack of homogeneity of the metallic deposit and its feeble adhesion to the cathode.

(3) To the variation of density of the several layers of liquid, the conductivity of which decreases with the density. These injurious reactions are the result of the attacking action, more or less energetic, of the electrolyte on the metallic deposits, giving rise to the formation of internal counter-currents.

Polarization is caused by the layer of hydrogen gas which is generated at the cathode surface and which sets up a current but in an opposite direction to the principal one.

In order to work as economically as possible,

(1) The resistance of the bath much be reduced to a minimum, and this can be done either:

(a) By avoiding all possibility of formation of short circuits, by which it would therefore enable the electrodes to be brought quite close together.

(b) By taking advantage of the condition of the metal produced.

(c) By making the bath of uniform strength.

(2) Polarization must be done away with by getting rid of the hydrogen as fast as it accumulates on the cathode.

The Tommasi electrolyser (Figs. 1, 2, 3, and 4) consists of a rectangular tank d, in which are placed two anodes p p, between which is placed the anode c, a metallic disc mounted on a gun metal spindle and capable of being rotated.

The disc is not entirely submerged in the bath, but only a part of it is, so that that part comes alternately in contact with the air and the electrolyte.

That part of the disc which emerges from the liquid, when the disc is rotated, passes between two scrapers, O, whose duty it is not only to scrape off the spongy deposit, but also to depolarize the surface of the disc.

The anodes can be either in the form of plates or of coarse powder. When used in a granular state, the compounds are simply packed in a perforated receptacle in the centre of which a metallic plate, to act as conductor, has previously been placed, and to make sure of there being good contact between the granular pieces and the conductors, a similar metallic plate is placed on the bottom of the receptacle on which they lie.

In the larger form of electrolyzers, the anodes are made up of two or more parts to permit of their being withdrawn, and replaced if necessary, without having to disturb the disc cathode. The disc is made all in one piece when the metal to be recovered is deposited in a spongy state; it is, however, made in several interchangeable sections when the metal is deposited in a compact state. The sections with which the cathode is built up are fixed to the spindle by means of bolts or screws, which can be unfastened when it is desired to replace any of the sections.

When the sections are coated with a sufficiently thick layer of metal they are withdrawn by a hook at the end of a chain, which is wound round a roller placed over the electrolyser. By a suitable arrangement the sections are taken to a bath of molten metal, similar to that deposited on the sections—into which they are dipped, the electrolytic deposit is melted in the bath and the sections can be taken back to the electrolyser to be again deposited upon.

The advantages of the Tommasi electrolyser over others are as follows:

A. In the case of metals which become deposited in a spongy state, as for example, lead.

1st. Polarization is entirely done away with

(a) By the rotation of the cathode disc in the electrolyte.

(b) By the rubbing action of the scrapers on each side of the disc, such operation helping to get rid of the hydrogen clinging thereto.

2d. The metal deposited on the disc is removed as the deposition proceeds, from which the following advantages are derived:

(a) The metal being continually removed from the oxidizing action of the electrolyte is not liable to be attacked and consequently to forming local couples by which the current set up is in the opposite direction to the principal current.

(b) A considerable diminution of the electric resistance of the electrolytic bath, since it is possible to bring the anodes

FIG. 2.—VERTICAL SECTION OF TOMMASI ELECTROLYSER.

and cathodes as close together as possible without any short circuits.

(c) Considerable saving in the consumption of electric energy, due to the diminution of the resistance as just stated.

3d. The density of the liquid in all parts of the electrolyser is the same, due to the rotation of the disc which keeps the

liquid agitated and mixed without interruption and consequently prevents its becoming saturated at the bottom and feeble in strength at the top, as is the case in ordinary electrolyzers where the liquid is at rest.

B. In the case of metals, for example, copper, they become deposited in a compact state.

The density of the layers of liquid which the current passes through, is uniform, owing to the action of the rotating discs, which agitates and mixes the liquid and consequently prevents its becoming saturated at the bottom and becoming weaker

FIGS. 3 AND 4.—PLAN AND HORIZONTAL SECTION OF TOMMASI ELECTROLYSER.

in strength near the surface, as is always the case in electrolyzers where the liquid is at rest.

Inasmuch as the Tommasi electrolyser can be advantageously employed in all electrolytical refining of metals, such as copper, lead, zinc, nickel, silver, etc., the recovery of tin from tinned iron scraps, the treatment of matts, the extraction of metals from their ores, more particularly zinc, copper, antimony, gold, etc., we shall only deal with the electrolytic desilverizing of argentiferous lead.

THE ELECTROLYTIC DESILVERISATION OF ARGENTIFEROUS LEAD BY THE TOMMASI PROCESS.

This process can be applied equally to argentiferous copper pyrites, as to argentiferous blendes, and other argentiferous minerals, but we shall only deal with the electrolytic desilverization of argentiferous lead.

The principle upon which this process is based consists in electrolyzing a solution of a lead salt, which has not only a very low electrical resistance, but also does not give rise to the formation of peroxide of lead. It is well known that the electrolysis of plumbic solutions nearly always leads to the formation of peroxide of lead, which in being deposited in the anodes forms a couple setting up a current in the opposite direction to the principal current, the effect being to increase the resistance of the bath and consequently also the e. m. f. necessary for its decomposition; and to use the argentiferous alloy itself as anode, the cathode being a disc made of metal, which is unattacked by the electrolyte. Under the action of the current, the lead in the anodes becomes dissolved and deposited as spongy crystals on the cathode disc, whereas all the silver in the alloy being insoluble in the bath falls to the bottom of the electrolyser in a perforated recipient put there for the purpose. In the event of there being antimony and arsenic present with the silver, they can be separated from it by fusing in a crucible with a mixture of borax and sodium nitrate. The antimony and arsenic are converted into antimoniate and arsenate of sodium respectively and all the silver remains in the metallic state.

The electrolyte used is a solution of the acetates of lead and sodium or potassium, to which are added certain compounds, the nature of which is kept secret.

The method of working is as follows:

The argentiferous lead is melted and cast into suitable molds. The $\frac{1}{2}$ anodes—each anode is in two $\frac{1}{4}$ circular pieces—are attached to four metal rods placed at the top of the electrolyser and which are each of them provided with a screw and bolt.

These are in connection with the positive pole of the dynamo. The anodes are so held that not only is it possible to keep the electrodes a fixed distance apart, but it is possible to bring them closer together as the anodes become used up.

The cathode disc is placed between the anodes and is in connection with the negative pole of the dynamo, contact being made by means of a metallic brush rubbing on the spindle of the disc. In working the discs made to make one or two revolutions a minute, the disc which is three meters in diameter is made of aluminum bronze, or of nicked iron. It may be made of copper or even of sheet iron. As soon as the current is turned on, the lead commences to be deposited on the disc in the shape of spongy crystals.

When the deposit of lead has been judged to be of sufficient thickness, and it is thought advisable to remove it, the current is switched off and the scrapers are applied. These scrapers are two brass or aluminum bronze plates, which by a simple mechanism can be brought close up against the disc or withdrawn, as the case may be. By the action of the scrapers, the lead is detached and falls into suitable "gutters" by which it is led to a sieve of metallic gauze. The lead is washed with distilled water and submitted to great pressure. The liquid which exudes is collected with the washings, and the whole is evaporated down till it reaches a density of 300 Baume. The solution is allowed to get cold and is pumped into the electrolyzers. The compressed lead is heated in a crucible with 2 to 3 per cent. of charcoal powder and cast into ingot molds.

When the anodes are dissolved, they can either be replaced by fresh ones, or the silver which has fallen to the bottom of the tank can be collected. In the latter case, the disc is raised by suitable means, and the perforated recipient, which had been placed at the bottom of the tank at the beginning of the operation, is taken out, as it contains all the silver which has fallen away from the anodes.

Theoretically, the extraction of silver from an argentiferous lead, or as it is most generally called, the refining of lead, by means of the electric current, does not demand any consumption of mechanical energy.

The amount of heat evolved by the solution of a molecule of lead as acetate is exactly the same as that absorbed by the setting free of a molecule of lead from that same salt.

The mechanical energy is, as a matter of fact, utilized solely to overcome the resistance of the bath, which acts as electrolyte and also the polarization of the electrodes. It should, however, be observed that the passage of a metal from the anode to the cathode must necessarily absorb a certain amount of mechanical energy, but this is so very small that it can easily be neglected.

In short, if it were possible to do away with the electrical resistance of the electrolyte and suppress the polarization of the cathode (the anode being soluble does not become polarized) the electrolysis of any salt, using a soluble anode made of the same metal as that of the salt in solution forming the electrolyte, would take place, not without using up no energy at all, but only an excessively small quantity of it and nothing in proportion to that needed in the refining of some metals, and chiefly in the case of lead, with which we are at present dealing.

It has been impossible up to the present to do away with the polarization of the cathode in the electrolytic refining of this metal, and to prevent the formation of peroxide of lead at the anode.

In the refining of lead, the resistance of the electrolyte and the polarization are due to the following:

As regards the resistance:

1st. To the distance the electrodes are kept apart, which must be at least 10 centimeters, for lead, as is well known, becomes deposited in the form of crystals, the volume of which is considerable (more particularly if a strong current is used), and would eventually lead to short circuits if the anodes and cathodes were not kept sufficiently far apart.

2d. Owing to the weakness with which it adheres, the lead deposit would very soon become detached from the cathode and fall to the bottom of the bath, if pains were not taken to frequently collect it, in fact, almost as fast as it is deposited.

3d. To the unequal density of the various layers of liquid the conductivity of which is less as the density diminishes.

With regard to polarization:

To the layer of hydrogen which becomes deposited in the

cathode, and which gives rise to a current which is in the opposite direction to the principal current.

In the Tommasi electrolyser, as has already been said, the resistance of the bath is considerably reduced by the possibility of bringing the electrodes closer to each other, even up to two or three centimeters, since the deposited metal being frequently removed, it cannot lead to the formation of short circuits.

As to the polarization, that is completely done away with by the rotation of the disc and the intermittent rubbing of the scrapers, when they are brought into contact with the sides of the disc, in order to take off the lead deposit.

To the important advantages of this process already mentioned, there is one other, none the less important, to be added, viz., the composition of the electrolyte. As a matter of fact, it is not easy to choose a good bath, particularly for the refining of lead, for that bath must satisfy certain conditions, on which depend to a great extent the success of the operation. These conditions are as follows:

- 1st. The resistance of the bath must be very low.
- 2d. During the progress of the electrolysis, there must be no crystalline or amorphous deposit on the electrodes.
- 3d. The lead deposited must be in such a state as to adhere sufficiently so as not to fall off, yet not so strongly as not to be taken off by means of the scrapers.
- 4th. It should dissolve out the lead only, without attacking the silver contained in the alloy.

These conditions are fulfilled by the use of an electrolyte, the composition of which has been given above, whose electrical resistance is very low, does not crystallize out, nor yields a deposit of peroxide of lead on the anodes, does not dissolve out the silver, and finally yields a deposit of lead which adheres well to the disc and yet is easily detached therefrom by means of the scrapers.

As the result of a large number of experiments, for an electrolyser of the following size and dimensions, the electrical constants, which we will give further on, can be taken as the basis of calculation:

Number of disc cathodes.....	I
Diameter of disc	I meter
Thickness of disc	.2 m. m.
Height of disc out of the electrolyte	.40 c. ms.
Surface of the disc submerged	2,910 sq. c. ms.
Material of which disc is made	copper or sheet iron
Revolutions of disc	I per minute
Number of anodes	.2
Thickness of anodes	I c. m.
Composition of anodes	argentiferous lead
Distance between the anodes	.4 c. ms.
Distance between an anode and a cathode	.19 m. m.
Composition of electrolyte	double acetate of lead and potassium
Current	.75 amperes
Resistance of the bath	0.00387 ohm
E. m. f.	0.29 volt

According to Ohm's law, for a given resistance the current varies directly as the e. m. f. on the other hand, if the surface of the electrodes is increased; in other words, if the resistance of the bath is reduced proportionately to the intensity of the current, the e. m. f. will remain the same.

The following are the details of an installation, which would be capable of desilverizing electrolytically by this process, from 25,000 to 30,000 tons of argentiferous lead per annum.

Number of baths in parallel ...	500
Disc and cathodes per bath	I
Diameter of disc cathodes	.3 meters
Thickness of disc cathode	.2 c. ms.
Nature of disc	Aluminum bronze
Anodes in each bath	.2
Thickness of anodes	.5 c. ms.
Nature of anodes	Argentiferous lead
Distance between anodes and disc	.2 c. ms.
Revolutions of disc	I per minute
Composition of electrolyte	Double acetate of lead and potassium

E. m. f. per bath	.0.75 volt
Total e. m. f. for the 500 baths (a)	.375 volts
Current	I,800 amperes
Conductor consists of 400 wires of 6 sq. m. m. cross section	
Length of conductor	500 meters

Resistance of conductor	0.0035 ohm
E. m. f. absorbed by conductor (b)	.63 volts
Total e. m. f. (a & b).....	.381.3, say. 382 volts
Energy absorbed	.687,600 watts
Power of dynamo	.721,980 watts
Motive Power	.980 h. p.
Cost of a 1000-h. p. engine	200,000 francs
I dynamo of 721,980 watts, or 5 each of 144,326	
watts	80,000 "
500 electrolyzers, including the electrolyte at 1,000	
francs	500,000 "
Total	780,000 francs

Conductor	\$156,000
Interest at 10 per cent. on 780,000 francs	20,000 francs
Interest at 5 per cent. on 20,000 francs	78,000 "
Coal assuming 800 grammes per h. p. hour at 15	
francs a ton	1,000 "
Oil and sundries	86,400 "
2 stokers	10,000 "
2 electricians	5,000 "
30 assistants	30,000 "
	215,400 francs
	\$43,080

Lead deposited in the electrolyzers.

In each bath, per hour ($1,800 \times 3.9$).....	7,020 grammes
In 500 baths, per hour.....	3,510 kilogr.
In 500 baths, in 24 hours.....	84,240 kilogr.
In 500 baths per annum of 300 days.....	25,272 tons

The cost of one ton of lead, therefore, comes to

$$\frac{215,400}{25,272} = 8.60 \text{ francs } (\$1.72).$$

If work was carried on every day throughout the year it would work out to $\frac{244,923}{30,747} = 8 \text{ francs a ton } (\$1.60).$

Using hydraulic power (waterfall) for driving the machinery, the cost of production of one ton of lead would be

(a) For 300 working days a year,

$$\frac{145,000}{25,272} = 5.80 \text{ francs } (\$1.16).$$

the cost of the desilverizing of the lead.

(b) For 365 working days a year,

$$\frac{152,794}{30,747} = 5 \text{ francs } (\$1).$$

The average cost of the electrolytical desilverizing of argentiferous lead works out at 6.85 francs, say 7 francs (\$1.40), a ton. If we assume two francs to include the cost of casting the anodes and of the lead and silver ingots, and incidental expenses at 1 franc, the total cost of the electrolytical treatment of argentiferous lead would certainly not exceed 10 francs (\$2) a ton. If, however, we consider that the ordinary process for refining lead costs at least 5 francs (\$1) more per ton than pig lead and that, on the other hand, electrolytic lead is much purer than the refined lead of commerce, the conclusion to be come to is that the electrolytic desilverizing of argentiferous lead would not in reality come to, at the most, 5 francs a ton. Notwithstanding these considerations, which nevertheless are not worthless, we shall assume as the basis of our calculations, 10 francs as being the cost of the complete treatment of a ton of argentiferous lead.

By this process argentiferous lead, poor in silver, can be advantageously treated, i. e., containing 150 to 200 grammes of silver to the ton, and even less, if the cost of fuel is not excessive, and, better still, if water power is available. It is just these poor ores which are the most abundant and the purest, and from which it is not possible to extract the precious metal by chemical processes, for the value of the silver would not cover the cost of the desilverizing of the lead. The following table will show better the advantages which this process for the electrolytic treatment of lead poor in silver offers:

Silver present in one ton of lead.

Cost of Tommasi process.....	10 francs (\$2) a ton
Cost of chemical process.....	30 francs (\$6) a ton

110 grammes.....	profit, 1 fr. (20c); loss, 19 fr. (\$3.80)
150 grammes.....	profit, 5 fr. (\$1); loss, 15 fr. (\$3)
200 grammes.....	profit, 10 fr. (\$2); loss, 10 fr. (\$2)
250 grammes.....	profit, 15 fr. (\$3); loss, 5 fr. (\$1)
300 grammes.....	profit, 20 fr. (\$4); loss, 0 fr. (\$0)
350 grammes.....	profit, 25 fr. (\$5); profit, 5 fr. (\$1)

This process cannot only be advantageously applied to the extraction of silver from argentiferous lead, but it can also be applied to many other important purposes, viz., the preparation of spongy lead for electrical accumulators, carbonate and oxides of lead.

Spongy Lead.

The lead recovered from the electrolyzers is a spongy mass composed of minute crystals, which are very light and very plastic, and in this state it is an excellent active substance for accumulators of any known system and particularly in the Tommasi accumulator, known as the Fulmen. Its plastic condition renders it easy of application to the electrodes of accumulators, and its fine state of division makes it a substance eminently suitable to be transformed rapidly under the influence of the electric current into peroxide of lead.

The spongy lead used by some manufacturers of accumulators is obtained by the addition of zinc to a solution of lead acetate. The lead thus obtained is not only more expensive than that obtained electrolytically, but it is far from being pure, since it contains the greater portion of the foreign bodies contained in the ordinary zinc of commerce, chiefly arsenic, bismuth and antimony, and the presence of these is detrimental to the good working of the accumulators and causes them to rapidly deteriorate.

As to the cost of production of a ton of spongy lead, it can approximately be taken from the following:

1,832 kilogs of lead acetate @ 650 fr. a ton.....	1,190.80 fr.
320 kilogs of zinc @ 450 fr. a ton.....	144 fr.

(This is the theoretical quantity. As a matter of fact, at least 500 kilogs are used.)

Labor	20 fr.
	1,354.80 fr.
	\$270.96

The acetate of zinc formed having no industrial application, its commercial value is quite insignificant; in fact, it is practically valueless.

By the Tommasi process a ton of chemically pure spongy lead would cost:

Lead anodes.....	250 fr.
Cost of electrolysis.....	8 fr.
	258 fr.

That is to say, in round figures, 260 francs.....\$51.60

The saving effected would thus be 1,355 - 260 = 1,095 fr. (\$219). Assuming an annual consumption of 1,000 tons, the adoption of this process would lead to the saving of 1,095,000 francs (\$219,000).

Lead Carbonate.

Lead Oxide.

According to the treatment to which the spongy lead obtained from the electrolysis is subjected, it is possible to produce either

- | | |
|----------------------------|---|
| (A) Unoxidizable lead, and | } (1) becoming converted into litharge or minium, according to the temperature; |
| (B) Oxidizable lead. | |
| | (b) becoming converted into carbonate. |
| (B) Oxidizable Lead. | |

When the electrolytic lead is acted upon by certain re-agents it becomes easily oxidizable and becomes very hot when in contact with air. The oxidation of the lead is nevertheless only partial, for it does not whiten and remains in a grayish powder. This powder, composed of finely divided lead, does not melt when heated in contact with air, but becomes rapidly converted into oxide of lead. It will therefore be possible to obtain from electrolytic lead, massicot, litharge, and even minium, in a very pure state and very cheaply.

It is estimated that the cost of production of a ton of oxide of lead prepared by this process will not cost more than 20 francs (\$4); i. e., its price would come to 270 francs (\$54) if lead

costs 250 francs (\$50) a ton; whereas, litharge and minium prepared by the ordinary processes cost at least 400 francs (\$80) a ton, from which it is seen that the Tommasi process leads to a saving of 130 francs (\$26).

In order to produce lead carbonate, i. e., lead becoming white when in contact with air, the lead obtained from the electrolyzers is submitted to treatment in an apparatus, by the aid of which it is possible to deal with large quantities of the lead. It may be added that this apparatus, being hermetically closed, there is no fear of any carbonate of lead dust floating about in the air, as is the case in the ordinary manufacturing process, and which is so harmful to those employed in its preparation. By this new arrangement this operation is perfectly harmless.

When all the lead has been transformed into lead carbonate it only remains for the product to be washed and dried on slabs of porous ware.

It would be well to estimate the cost of production of lead carbonate by the electrolytic prices and to see the saving effected by it over the ordinary process of manufacture.

The composition of lead carbonate varies according to the process by which it is manufactured. The formula which most nearly corresponds to the ordinary commercial carbonate of lead can be taken as 4 P.C. CO₂, P CO₂H₂O. From this formula it follows that for the production of one ton of carbonate the amount of lead theoretically required would be 715 kilogrammes, practically 800.

We have already seen that the cost of production of a ton of electrolytic lead was at the most 10 francs (\$2), and consequently a ton of lead carbonate prepared by our process can be approximately estimated to cost:

800 kilogrammes of ordinary lead for making anodes @ 250 fr. a ton.....	200 fr.
Cost of electrolyzing.....	8 fr.
Cost of making lead carbonate.....	20 fr.
	228 fr.
	\$45.60

Lead carbonate made by the ordinary process costs about 430 francs (\$86) a ton, taking the price of lead at 250 francs (\$50) a ton. The saving in cost of production by our process would therefore be 430 - 228 = 202 francs, say, 200 francs (\$40) a ton.

The method just described is not only eminently practical, but also very economical. It must consequently, and in a very short time take a leading place in the electro-metallurgical industry.

The Soot of Acetylene Flame.

The soot of the acetylene flames represents a valuable product, especially for the color industry. When acetylene gas is burned with a smoking flame three or four times as large a quantity of soot is obtained as from the same quantity of mineral oil. The acetylene soot is very light and exhibits an absolutely black color without any tinge of brown. Besides, all tarry admixtures and other substances contained in lamp black, etc., are absent from the soot. It is very bulky and will be specially adapted for India ink, as well as for colors used in printing and lithography. A recent French patent issued to E. Hubon gives three methods for the production of the color. According to the first the acetylene gas is kept in a steel cylinder under two atmospheres pressures and is then ignited through an electric spark or a glowing platinum wire by way of explosion. The final pressure of the resulting hydrogen does not exceed twelve atmospheres, so that the danger of an explosion is excluded if steel cylinders of corresponding strength are employed. This method has the advantage that the theoretic yield of carbon is obtained from the acetylene, the product being of the greatest purity.

NATCHEZ, MISS.—A contract for a term of ten years for electric lighting has been made by the city with A. & M. Moses, who offered 100 arc lights at \$103 per annum; city incandescents, 15 cents per k. w.; private arcs, etc., at 18 cents per k. w. The concern gives bond in \$15,000, and will at once erect a power house, plant, etc.

ST. LOUIS, MO. The Bell Telephone Co. is introducing slot telephones, on a percentage basis, chiefly in the drug stores.

Power Transmission and Distribution for Railway Work.¹

BY ERNST J. BERG.

WHEN electric power was first applied to railway work, the distances of transmission were comparatively short, so that one generating station usually located in the centre of distribution was sufficient to furnish all power at a reasonable loss.

As the plants were extended it was soon evident that even disregarding the question of efficiency, the distances were very limited for commercial and practical reasons, and boosters connected in series with the line so as to raise the voltage proportional to the load were introduced. By their use it was possible to cover considerable distance and yet keep the potential up without too excessive an amount of copper. Since, however, any booster system must be very inefficient, such installations are not very common, and their field of usefulness limited to cases where considerable power is taken and at the end of a long line for a short time only. The next step toward extension was the introduction of power stations located in various places in the network, but the complication and inefficiency of such an arrangement was apparent, and the possibility of transmitting the power by alternating currents was brought out.

The first suggestion was to generate alternating current power in one station and transmit it at a reasonably high voltage to various sub-stations placed where the steam stations would have been located under former conditions, and there convert it to direct current by means of synchronous motors driving direct current generators. This method of transmitting and converting electrical power was applied in a few cases, but was soon superseded by the converters which not only gave a simpler means of converting alternating current to direct current, but which are more efficient and permit of perfect automatic potential control. Thus in 1894 large and representative converter systems were installed.

Since, with the introduction of long distance transmission the generators were placed far away from the converters and connected to them by lines of considerable resistance and self-induction, it was apparent that potential control could hardly be effected in the power station, at least a control of sufficient sensitiveness to follow the greatly fluctuating loads in a railway circuit, the more so as the voltage does not vary in the same proportion as the load.

It was therefore necessary to develop some means by which the potential could be controlled, not at the generator station, as is done in direct current railway circuits, but in the converter station. This means of regulating the potential was found in changing the phase relation of the current taken by the converter by means of a change of field excitation, raising or lowering the impressed alternating voltage, and consequently the direct current voltage by means of this current passing through lines of considerable self-induction, or through special reactive coils inserted in the circuit.

In the following I shall endeavor to explain this method of control, and discuss its effects on the operation in general.

In a synchronous converter system we have to distinguish between three e. m. f.'s; the impressed e. m. f., that is, the e. m. f. at the collector rings of the rotary converter; the counter e. m. f., which is the e. m. f. induced in the rotary converter by the armature revolving in the magnetic field, and consequently proportional to the field excitation; and the e. m. f. of impedance or the e. m. f. consumed by impedance, which is that caused by the current flowing through the reactance and resistance of the system.

The first mentioned e. m. f., that is the impressed e. m. f., is entirely dependent upon the generator voltage; the counter e. m. f. is entirely dependent upon the field excitation of the converter, and is constant regardless of the load on a machine,

and the e. m. f. consumed by the impedance changes with the load and is proportional to the current.

To explain the phase relations between these e. m. f.'s. let us for the sake of simplicity consider the converter running light or doing no work. Since the work done by a synchronous converter rotary is the product of the current taken by the rotary and the projection of the counter e. m. f. on this current at no load the current must be in quadrature, that is, at right angles to the counter e. m. f. Since, furthermore, the input of a rotary converter is expressed by the product of the impressed e. m. f. and the projection of the current on the impressed e. m. f. under the assumption that no energy is consumed, the current is also in quadrature or at right angles to the impressed e. m. f. Consequently the impressed e. m. f. and the counter e. m. f. must be in phase and in opposition to each other. Let, then, the field excitation of the converter be reduced, so that the counter e. m. f. is less than the impressed. Since only three e. m. f.'s. are acting in the system and their sum must always be zero, that is, the impressed e. m. f. must at any time be equal to the counter e. m. f., plus the e. m. f. consumed by impedance or neglecting the resistance, the e. m. f. consumed by the reactance. The counter e. m. f. is assumed to be less than the impressed, therefore, the e. m. f. consumed by reactance must be in phase with the counter e. m. f. and itself thereto. But since the current is always 90° ahead of the e. m. f. of self-induction it must be behind 90° the impressed e. m. f. and consequently be lagging.

If, on the contrary, the field excitation of the converter is increased so that its counter e. m. f. is higher than the impressed, it is evident that the e. m. f. consumed by reactance must be in phase with the impressed e. m. f. and add itself thereto. Consequently since the current is 90° ahead of the e. m. f. of self-induction it must be also ahead of the impressed e. m. f., in other words, the current is leading. By a similar discussion it is readily seen that the same argument is true, if the converter is loaded. That is, in this case the wattless lagging or leading current due to the difference between counter e. m. f. and impressed e. m. f., merely adds itself in its proper phase relation to the energy current representing the load.

It is thus seen how by means of converter, leading or lagging currents are caused to flow in the lines. It is readily shown how the voltage at the receiving end of the system can be changed by causing a leading or lagging current to flow over a line with some self-induction.

After showing this graphically, Mr. Berg continues by giving an analytical treatment in the course of which he said:

Usually it is required that the converter voltage shall remain constant or increase with the load, when the generator voltage or excitation is kept constant. If each converter is operated from its own generator, it is preferable to leave the generator field excitation constant and thereby use the generator reactance for phase control and avoid any necessity of regulation in the generating station. If, however, many converters are operated from one generator, or if all generators in the power station are operated in multiple, it is preferable to keep the generator terminal voltage constant, and control the converter voltage by outside reactances in a low reactance transmission, or by the line reactance in a highly inductive transmission.

It may perhaps seem as if it would be rather a delicate operation to accomplish this potential control in commercial circuits where available instruments, etc., would prohibit the determination of leading or lagging currents necessary for the control with any degree of accuracy, yet the problem is perfectly simple and resolves itself to adjusting the shunt excitation for a given running light current which is predetermined by calculation, and afterwards to adjust the series field so that the converter takes minimum current, that is, runs non-inductively at the desired load.

It will then follow that the potential control for all intermediate loads is perfect, at least within very close limits, as I shall show later.

The author then showed plainly by means of curves that the smaller the loss the smaller is the running light current and the smaller reactance is necessary. In a system of 5 per cent. loss 30 per cent. reactance, that is such a reactance should be inserted as gives 30 per cent. of rated voltage at full load current. In a system of 15 per cent. loss, however, 50 per cent. reactance would be about as low as we would go, and yet the running light current is 50 per cent. of full load current.

¹Abstract of a paper read at the 15th General Meeting of the A. I. E. E., Omaha, June, 1898.

It is evident also that the more energy loss, the higher should the generator voltage be relative to the converter voltage as shown by the equations.

In the above case we assumed that the converter should run non-inductively at full load; usually, however, it is preferable to run it non-inductively at a somewhat lighter load, say $\frac{3}{4}$ load.

In this case with 40 per cent. reactance, the running light current is only 20 per cent. of full load current at 10 per cent. energy loss, and with 50 per cent. reactance only 34 per cent. at 15 per cent. energy loss. Therefore it would indeed seem, as if it always were more favorable to run with non-inductive load at $\frac{3}{4}$ load. This is still more evident, when investigating the power factor curves with these adjustments, yet there are some reasons why sometimes converters are adjusted for non-inductive load at full load as will be seen.

The maximum output of a converter is practically unlimited provided the generator voltage can be increased, and there is sufficient capacity behind the generator.

To obtain the maximum possible output with a given line impedance, the converter should run non-inductively at higher outputs as the generator voltage increases, so that for instance, if the system has 10 per cent. energy loss and 40 per cent. reactance and the generator voltage is kept $12\frac{1}{2}$ per cent. above the converter voltage, the maximum output is 2.12 times rated output and the converter should run non-inductively at $\frac{3}{4}$ of rated load. If the generator voltage were 18 per cent. higher than the converter voltage, the output would have been $2\frac{1}{4}$ times the rated, and the converter would run non-inductive at full load and finally, if the generator voltage were 30 per cent. higher than the converter voltage the maximum output would be 2.55 times the normal output, but the non-inductive load would have been $1\frac{1}{2}$ times full load. In other words, the converter should run with lagging current up to 50 per cent. overload.

In commercial installations, however, where there is always a limit to the generator voltage, which limit is caused by saturation of the machine, or outside conditions which do not permit of excessive voltage in the power station, the output of a converter is by no means unlimited, and thus some care has to be taken, to get the proper reactance, since with a given difference in generator and converter potential, the output changes as we change the reactance and resistance.

To show that the output of the converter depends also necessarily upon the resistance of the line, the author presents several curves and continues as follows:

As seen, the output increases very rapidly as the energy loss decreases at least within commercial conditions, that is between 5 and 20 per cent. loss. The maximum output with 40 per cent. reactance and zero resistance would be three times rated output.

With 5 per cent. energy loss the maximum output would be 2.6 times rated output, and the converter should be adjusted for non-inductive load at $\frac{1}{4}$ full load.

The condition which is to be met with in a commercial installation is, that the generator is limited to a certain value, that the converter voltage shall be maintained constant at all loads or increase with the load, and that there shall be a certain margin in maximum output and the highest power factors at all loads.

In practice the shunt field is so adjusted that the converter takes the required lagging current running light, and the series field is made to increase the excitation so as to give the required field strength at non-inductive load. Since, however, the series excitation is proportional to the load, it is evident that without hand adjustment, it would be theoretically impossible to accomplish perfect phase control; or rather, it would be impossible to have constant voltage at the rotary converter with constant voltage at the generator. The difference, however, is exceedingly small, the series field being slightly too strong at light loads and too weak at overload, in other words, the voltage will be slightly increased at the converter up to non-inductive load and will drop slightly at overloads.

In the preceding we have not considered this point and have assumed that the theoretical loading or lagging current can be obtained at any load. Consequently the values which we have given of maximum output of the converter are not quite true in practice but the output is always less. The amount of this

decrease in output depends upon the magnetic characteristic of the machine and can readily be determined in practice.

Before closing the paper it might be well to discuss the conditions which govern the amount of reactance, etc., in the machines. As stated in the beginning of the paper, in plants where one converter is operated from one generator it is convenient to use the generator reactance for phase-control. Since, however, as seen, it requires considerable self-induction to do this at high power factors, it means a generator of high armature reaction and self-induction, in other words a generator with rather limited output with constant field excitation. This is not objectionable, since by leading or lagging currents the output can really be made as high as desired, even if the armature reaction is high. Yet when considering that it is often desirable to start the rotaries from the generator and therefore its voltage may be reduced greatly at the starting moment when the converter necessarily takes a large lagging current, it may not always be the best policy to use the generator reactance alone for phase control. Often, however, converters are started from the direct current side and sometimes by auxiliary motors. Under these conditions the generator might conveniently be made with very high armature reaction.

In plants where several converters are operated from the generator, or from a number of generators in parallel, control by generator reactance is not to be recommended, since it involves the change of series field adjustments with the change of generator capacity. The generators may be made of any armature reaction since several of them are used in parallel in starting, yet it must of course be borne in mind even then, that if the armature reaction is too high, the large current taken in starting a converter from the alternating current side, may cause the voltage to drop so far as to seriously disturb the system in general.

Regarding converters themselves, it is obvious from the preceding discussion that they must be of composite type, that is, they must have shunt and series excitation.

Shunt wound converters do not permit of automatic phase control, but at constant adjustment of the field will always run at the same wattless current at all loads, so that, for instance, if the field is adjusted for non-inductive load at one load the converter will run non-inductively at all loads, and therefore the drop in voltage at full load will correspond to the energy loss in the system, and the converter voltage will be higher at lighter loads than at heavier loads, therefore will vary as the load varies, and phase control is thus feasible only by hand regulation, that is, in systems where the load varies only slowly as in lighting circuits.

Reaction converters take lagging currents at all loads and thus are in general objectionable, the more so as they do not allow any automatic potential control.

Charging Station for Paris Automobiles.

AS a matter of interest to many of our readers, we illustrate herewith the charging station at Levallois, Paris, for electric automobiles, Fig. 1 giving a general view and Fig. 2 showing

FIG. 1.—AUTOMOBILE CHARGING STATION, PARIS.

ing the light switchboard used in some of the work, with its meters, rheostats, signals and connections. Such a board is portable and can be readily transferred from place to place. It

is worthy of note that in Fig. 1 all the carriages are shown as being charged with the batteries still in them, although the Victoria in the foreground has its battery box open, as if for new cells. In this country, so far as the use of electric automobiles is concerned, while it may be the practice to charge batteries in private vehicles, in situ, those for the public vehicles

FIG. 2.—AUTOMOBILE CARRIAGE SWITCHBOARD.

are not so charged but are removed when exhausted and newly charged cells are run into the box, so that the same carriage can go out at once into service again in a few minutes. It is obvious that if a carriage has to be charged with its batteries on board, the owner is likely to be deprived of its services for several hours when he may most need it.

BY A. E. DOBBS.
SWITCHBOARDS.

RING-OFF drops cannot at present be used by independent exchanges, and they are not really necessary as a non-inductive resistance can easily be shunted around them so that while the drop is still in circuit it will have no perceptible effect on the conversation.

One way in which this can be done is shown in Fig. 53. The line coming into the board is shunted to the jacks P P, thence to the drops D D, after which it is joined to the common return or ground wire G.

As will be seen, the cords are connected together through a non-inductive resistance, R, which shunts the larger part of the current around the drops, but leaving enough to ring off with. For ringing and listening the jacks may be movable or regular ringing and listening keys placed on the table in front of the operator.

Another plan sometimes used is to have switchboard coils of 1,000 ohms each and have them bridged on the line leaving them in circuit for ringing off.

Those who prefer switchboards used by the Bell companies can procure them from the Sterling Electric Co., of Chicago, they having made arrangements with Mr. Frank B. Cook to manufacture his apparatus jointly with the Western Electric Co., and many old Bell men have a strong partiality for the appliances they are familiar with.

In switchboards of this kind (shunted and bridged) there is

liable, however, to be considerable cross talk from the close proximity of the coils to each other, which would be absent if they could be cut out, but this can be avoided by the use of an iron shield which entirely surrounds it, thus screening the inductive effects (Fig. 54). The oldest of these is the tubular shield, the invention of Mr. Frank B. Cook, which entirely surrounds the spool, and is simply a soft iron tube of about No. 16 B. W. G. in thickness. Another form designed to evade this patent and apparently as efficient, is a shield made of half a tube, placed above the magnet spool, and covering fully half of it. Placed in rows, as they are, each drop is shielded from the one either above or below it.

Others have tried wrapping the coil with ordinary tin plate,

FIG. 53.

but this is hardly enough, unless there are several turns. The back of the board might also be made up in squares like boxes in a post-office, and each drop placed in its own separate box. This little matter does not seem very important, yet as many of the new exchanges are badly troubled with cross-talk, and as most of it can be traced to the switch and cross-connecting boards, it will be seen that it is a little detail worth attending to.

One of the most frequent causes of switchboard trouble are the cords; as the perfect plug for holding the ends of these cords has not yet been invented, the only thing to do is to caution the operators not to pull on the cord in removing plugs, but to always catch the handle.

In some boards, too, the plug rests on a ground plate so that in answering calls, the operator merely has to plug in. If the plate contact, however, is made through a collar at the base of the plug, there is liable to be unsatisfactory service owing to dust and loose connection between this collar and the ground plate.

BATTERIES.

For ordinary telephone work batteries of the sal-ammoniac type are the best, as they are cleaner, less troublesome and last longer than any other.

By sal-ammoniac cells are meant such cells as the carbon cylinder, or Leclanche, in their various forms, in which carbon

FIG. 54.

combined with manganese, zinc and a sal-ammoniac solution are used.

The oldest, most costly and least efficient of these is the Leclanche porous cup cell, as it has a higher internal resistance, makes more trouble from creeping salts and is shorter lived than any of the carbon cylinder kind.

Most of the independent companies have found this out and have left it in sole possession by the Bell companies, whose reason for continuing its use is something of a mystery. I have never seen this battery used in places where a Samson Laclede battery or a similar type wouldn't do even better.

The main thing in a telephone battery is to get one that will last as long as possible with the least amount of attention. In order to prevent evaporation it should have a closed cover. I

have known cells of this kind to last a year without any attention whatever, which cannot be said of any Leclanche cell I have ever seen. In well regulated exchanges, however, some one should make a practice of visiting, inspecting and testing every instrument at least once every six weeks, taking particular note of the batteries.

The internal resistance of batteries is a matter of less consequence than the number of volts they produce, as the current going through the primary circuit is nearly always less than .25 of an ampere.

The best battery for the operator's instrument is the old-fashioned crowfoot gravity cell, because in this case the transmitter is in circuit all the time and they are the only kind that can be relied upon for constant long continued work. On the ordinary granulated transmitter four cells is about the right thing.

With toll line instruments a battery giving a higher electromotive force is desirable, and the standard Fuller cell fulfils the requirements more nearly than any other.

The American Bell company lays down the following rule: "When used in connection with long distance lines, it is recommended that a battery be used which will, at all times, give a current of more than .42 of an ampere at the end of one minute after the battery has been disconnected from the transmitter and connected in circuit with an ammeter and a resistance of five (5) ohms."

It will be noticed that this is the minimum current allowed and as they usually prescribe two of these cells, they can easily get double the amount of current specified.

This cell is set up in a 6 in. x 8 in. jar, and is made up of two solutions. The porous cup in the centre contains a strong solution of salt and water with about a teaspoonful of quick-silver added and also contains the zinc.

In the outer jar, which contains the carbon, is used electro-poin or the fluid made according to the following formula:

Solution for Outer Jar.

Sodium bichromate.....170 grams (6 oz.)
Sulphuric acid.....492 grams (17.3 oz.)
Water (soft).....1,600 c.c. (56.5 oz.)

Dissolve first the sodium bichromate in the water, and then add, very gradually, the sulphuric acid. To prevent overheating, the jar should be surrounded with cold water. If the solution is mixed direct in the 6 in. x 8 in. jar, see to it that the jar does not rest on a wet board or metal sink.

The following represents the approximate current, resistance and e. m. f. of the different batteries, which the Globe Carbon Works will guarantee, and other firms will doubtless do the same, if asked:

	E. M. F.	C.	Int. R.
Carbon cylinder pencil, zinc	1.5 ¹	1.5	1 ¹
Carbon cylinder circular, zinc	1.55	6	.26
Leclanche porous cup	1.5	1	1.5 ¹
Crowfoot, gravity	1	5 ¹	2
Standard, Fuller	2.2	5	.44
Globe carbon dry cell	1.6	12	.15 ¹

As said before, however, the internal resistance does not count so much on the average transmitter as the e. m. f.

For example, take the carbon dry cell, which shows a current of 12 amperes with an internal resistance of only .15 of an ohm on a transmitter having a resistance of 18 ohms, a coil, let us say, of .1 ohm. Using two cells we have then:

Internal resistance 3 ohm
Transmitter circuit 19 ohms
E. m. f. 3.2 volts
Current, $3.2 \div 19.3 = .16$ ampere.

Taking the Fuller cell, which has three times the internal resistance and only half the current on short circuit, we have:

Internal resistance 9
Transmitter circuit 19
E. m. f. 4 volts
Current = $4 \div 19.9 = .2$ ampere

Further comment is unnecessary. Nor is this all. In measuring a transmitter circuit with a Wheatstone bridge and galvanometer, we get, when at rest, say, 18 ohms, but talk into the transmitter and the resistance will rise to 30 or 40 ohms, due to the self-induction of the coil so that the amount of current will be only about half that given above, which makes

the matter of internal resistance of still less importance.

In setting up sal-ammoniac cells many people use too much sal-ammoniac. Use only a trifle more than the water will dissolve and a longer life and just as much current will be obtained.

Farm Telephony in Michigan.

A special dispatch from Grand Rapids, Mich., of Aug. 1 says: Michigan farmers are taking kindly to the telephone and it is probably but a matter of a few years when the telephone will be as common in the country as it is in the cities now. In Allegan County the farmers have an exchange of their own and they maintain it by annual assessments. The line runs from Holland, through Saugatuck, Ganges, Douglass and Fennville to South Haven, and it is used chiefly during the fruit season to facilitate the handling of berries and peaches. About 130 farmers and fruit growers built the line and maintain it, and the annual assessment upon each is about \$10.

Every township in Oceana County has telephone connections with Hart, the county seat, and this system is essentially a farmers' exchange, and is owned and maintained chiefly by the farmers and fruit growers. The Oceana County system, as also the Allegan County fruit growers' line, is being connected with a State exchange, and before the peach season fairly opens the farmers in both sections will be in easy talking range of the commission and railroad men here and the steamboat men at the lake ports.

Gratiot County has another farmers' exchange which, with Ithaca as the centre, has connections with every township and many farmers. The system gives free service throughout the county to its subscribers and will soon be connected with the outer world. It is a great advantage to the farmers in marketing their products.

Farmers living near the cities are having the telephone wires extended out to them, though the movement is still in its infancy. The Citizens' Exchange in this city has about a dozen farmers on its list, and that it has not a hundred or more is due to the rush of construction work in the city since the exchange was established. The first country telephone was to a farmer about a mile west of town. With direct connection with town he could sell his stuff in advance, arrange for his deliveries, and easily keep his finger on market conditions. It gave him a big bulge upon the other farmers, and it did not take his neighbors long to find it out. The line now runs out about five miles and all the substantial farmers along the line have hitched on. The farmers north and northeast of the city are clamoring for connection, and in another year they will probably be accommodated. The lettuce growers just south of the city all have connections, but they are so close to the city they are hardly called farmers.

Independent Telephony in Maryland.

The officers and Board of Directors of the Interstate Telephone and Telegraph Company held a meeting at Frederick, Md., on July 26. Mr. L. A. Carr, of Durham, N. C., the president of the company, was present, as well as the following officers: Vice-president, Dr. P. D. Fahrney; secretary and treasurer, J. S. Carr; local superintendent, John J. Murray; Board of Directors, Messrs. Dr. P. D. Fahrney, G. W. Watts, Jas. E. Walker. The business of the company is in a most satisfactory condition. Besides the 300 telephones in the city, the following county towns are on the circuit; Adamstown, Buckeystown, Buckeystown station, Ceresville, Ellerton, Feagaville, Frederick Junction, Harmony Grove, Ijamsville, Pearl, Jefferson, Le Gore Station, Lime Kiln, Middletown, Mt. Pleasant, Monrovia, Myersville, New Market, New Midway, Routhland, Urbana, Walkersville, Woodboro and New London. In a little while the towns of Braddock, Liberty and Ladiesburg will be connected.

Payment of Telegraph Tax.

The Western Union Telegraph Company has secured a restraining order against the North Carolina Railway Commission's order of 1897, reducing the rate on ten-word messages from point to point in the State from 25 cents to 15 cents, and also against the order of July 13, reducing the rate from 25 to 24 cents, in order to make allowance for the one-cent war tax stamp.

¹Approximate.

CINCINNATI, O. The City and Suburban Telephone Association has sent to the Army and Navy League its check for \$500, Col. G. N. Stone, general manager, writing that it "desires to express its admiration for the bravery displayed, and appreciation of the services rendered by our gallant soldiers and sailors at the front." The fund is for wives and children needing temporary assistance.

DETROIT, MICH. The Detroit Switchboard and Telephone Company has increased its capital stock from \$100,000 to \$250,000. The company's apparatus is to be supplied to a large new telephone exchange for which plans have been made and the capital raised in New Orleans. It is to have a board with 5,000 drops.

INDIANAPOLIS, IND. The New Telephone Company has awarded the contract for 265,000 feet of conduit pipe for its underground system to the H. B. Camp Company, of Aultman, O., and will prosecute briskly the work of laying it, having now, it is said, 3,000 subscribers assured.

SCRANTON, PA. The Lackawanna Telephone Co. has made an appeal to the citizens for a liberal franchise, promising to put up an exchange second to none in the country and to cut rates in two.

TERRE HAUTE, IND. The Citizens' Telephone Co. has given a contract for poles to the Kerby-Dennis Co. of Marinette, Wis., the poles to be No. 1 live peeled white cedar.

DETROIT TELEPHONE CO. is being sued by the Western Electric Co. for alleged infringement of switchboard patents, asking an injunction.

LIGHTING BY ACETYLENE. By Wm. E. Gibbs, M. E. New York: D. Van Nostrand Co., 1898, 5x8. 141 pages, cloth. Price, \$1.50.

Of late the manufacture of calcium carbide and the rapid introduction of acetylene for lighting purposes has brought the question of the production of these two agents, as well as the apparatus for the use of the latter prominently before the public. And while the art of lighting by acetylene seems far from being on a permanent, or even satisfactory basis, it seems to have been sufficiently advanced to have its progress up to the present date collected and, after careful sifting of the material on hand, to publish it in book form. The author has certainly presented the matter in a most interesting and instructive manner, and the little volume contains much matter of general interest on the following subjects: History of acetylene, electric furnaces, generation of acetylene, the impurities of carbide and purification of acetylene, generators of various types, acetylene lamps, and burners, the author's own experience, concluding remarks on the state of the art in this country, fire regulations for the installation of acetylene gas generators and a complete list of United States patents bearing on the subject.

THE TELEPHONE. By W. J. Hopkins. New York: Longmans, Green & Co., 1898. IX—83 pp., 5 x 7 1/4 in., 49 illustr. Cloth. Price, \$1.

This little book by the author of "Telephone Lines and Their Properties" has the commendable qualities of the earlier publication. In the preface the author states that he has "avoided making a descriptive catalogue of instruments and has endeavored to set forth the facts and principles in such a way that they will be easily and clearly understood." An introductory chapter on sound gives the knowledge requisite to an understanding of the book. In a short chapter the early history of the Reis and Bell telephones are considered. Then follows a scientific description of the development and working of transmitters. The systematic investigations on the working of the receiver and transmitter which have been

carried on for the last ten years at the Massachusetts Institute of Technology are given due notice and their part in the development of the transmitter shown.

The book is excellently illustrated, the language clear and concise, and the statements are correct. This little book should be in the hands of all who desire to understand the telephone transmitter and receiver. A.

MR. EDWARD WESSELS (formerly managing director of the Standard Air Brake Co.), who is the owner of the illustrated weekly newspaper, the "Universe," has just purchased all right, title and interest in "Sunbeams" Magazine. "Sunbeams" has been in existence seven years, and enjoys excellent advertising patronage, as well as a large subscription list. Mr. Wessels will merge "Sunbeams" into the "Universe"; the publication offices will be at 150 Fifth avenue, New York City. The "Universe" has rapidly worked its way into favor, and now goes to all parts of the world.

"FACTS ABOUT THE SOUTH" is the title of a valuable and interesting pamphlet on the advance of the South, and detailing the possibilities there, by R. H. Edmonds, editor of "The Manufacturers' Record," Baltimore. It contains thirty pages crowded with useful and suggestive data. The price is 20 cents.

MR. HIRAM S. MAXIM arrived in this country on Saturday from Europe, for a stay of three or four months.

MR. G. A. LORING is the new superintendent of the San Francisco and San Mateo Electric Railroad, vice Mr. S. B. McLennan, who has resigned. Mr. W. Clayton, secretary, will be the chief executive officer of the road.

MR. ERNEST GONZENBACH, electrical engineer, who has been associated with power transmission work in this country, has become superintendent of the Chambly power plant at Montreal, Canada.

MR. G. W. MANSFIELD, of Melrose Highlands, Mass., was in New York City recently. He reports that he is still actively engaged in electric railway work and says he will be glad to hear of any such enterprise that needs pushing or reorganization.

MR. JOHN A. BRILL, whose name appeared as that of a director in the new General Electric Automobile Company, of Philadelphia, finds that owing to the great rush in the car building business of the J. G. Brill Company he is unable to serve in that capacity.

MR. W. D. SARGENT, president of the International Brake Shoe Company, left recently for Europe to make arrangements for the manufacture of the Diamond "S" shoe in several European countries, including Russia. The success of this shoe since its introduction last fall is said to have been little short of phenomenal.

MR. ALFRED J. THOMPSON, a young engineer, who has been personally identified with Mr. Edison since his graduation from an English college in 1889, is about to leave the United States for a long and indefinite period. During his years of intimate association with the "Old Man" he made frequent visits to Cuba, where, through influential relatives, he installed several electric light plants and supervised other electrical interests. He has acquired such a thorough knowledge of the Spanish language as to prove a capable representative for the many American interests now being entrusted to his care. Mr. Thompson will have his headquarters in Havana, from where he will direct the operating plants under his control and extend "feeders" for the extensive business which he and his hustlers intend to build up. When Mr. Thompson was seen a few days ago he had completed his arrangements with nearly every firm whose products will be necessary for his electric light, telephone and traction work, and for those who would be represented in that hereafter prosperous island they would do well to have such a well endorsed and able man to push their goods and have their products in on the ground floor of the industries which are sure to concentrate there under the Stars and Stripes, and to be in there before the "surely coming" avalanche of American capital and energy arrives there.

Vol. XXVI. NEW YORK, AUGUST 11, 1898. No. 536.

The Detroit Municipal Convention.

NOTE is made in our pages this week of the meeting at Detroit of the League of American Municipalities. It appears to have been a serious and well designed effort, but one may doubt whether it was much of a success. Very little work apparently could be got out of the delegates, but all the entertainments drew big crowds. Even the entertainment feature, however, had a disagreeable aspect given to it. The city council had voted \$5,000 for junket, but a number of the citizens intervened, and secured first a preliminary and then a permanent injunction restraining the city and the Board of Education from expending these funds. Such a step had in fact been anticipated up in Massachusetts where a town appropriated money to send its mayor and aldermen to the meeting, but were prevented by an injunction. So what with would-be guests held back by law and would-be hosts also forbidden by law from entertaining, the League meeting at Detroit cannot be said to have been an altogether happy performance.

After all, the entertainment part should matter little, and Secretary Gilkison was right when he said they did not want it because it distracted the delegates from their work. Many a convention has been spoiled in this way. But the fundamental reason why the papers read were so poor and why the audiences to hear them were so meagre lay in the very make-up of the League. We cannot do better than quote one of its own members: "There is no profit in it for the delegates who come to the conventions. The stove manufacturers of the country, for instance, will hold a convention and the business meetings will be attended by every single delegate. Every word of every speaker will be eagerly listened to and the men will go home with new ideas and large amounts of information that will enable them to produce stoves more cheaply and therefore increase their own profits.

"With these fellows, it is entirely different. They hold their offices by the votes of the people. At best their time in the positions is limited. What do they really care about sanitary measures or street paving or garbage disposal? It's no money in their pockets. The interest of men in things that are not entertaining or amusing in themselves is measured by the amount of money there is in it. No money, no interest. That's all there is to it. Gilkison is the only man I have seen from outside of Detroit who is deeply interested in the convention. The Detroit people are interested in the entertainment end.

"The fact is the success of the association largely depends on use of public money for sending delegates to the convention. A council in a Massachusetts town appropriated money to send the mayor and aldermen here. An injunction was obtained from the courts, and the delegates didn't come."

There is a lot of hard, solid truth in this. The stove manu-

facturers, like the electric light men, or the civil engineers, are in their business to stay. Each convention adds to their stock of knowledge or to their list of professional acquaintances and friends. But it is obvious that the personnel of the municipal league must vary tremendously from year to year, depending on the political fortunes of its constituent members, and we all know that a mayor who succeeds himself in the United States is a rare bird; while for an alderman to remain long in office is equally unusual. When we come to the rank and file of city officials in charge of specific departments, they also have but too often a precarious position, and as we understand it are not exactly the kind of men who attend the League meetings. Such men go off by themselves like the municipal telegraph superintendents meeting this week at Elmira, or like those attending fire brigade conventions. It would certainly seem far more natural that city officials wanting to keep in touch with the work they represent would attend the meetings of societies devoted to that work and not conventions discussing casually all manner topics from the saloon and the social evil to toll bridges and municipal choral societies.

Another thing is that necessarily all who go to such a convention as that of the League, go to report "successes" or to help personal booms of one kind and another. Now a convention is an experience meeting, and the discussions bring out the things and methods that failed. But no mayor and no official is going to come away from home and report the failure of some pet scheme; nor is any insistence likely to be laid on disaster. Prof. Bemis, for example, enlarged on municipal ownership of lighting plants. Did he give the data of plants that had broken down, failed, been sold, had gone out of existence, or do not come up to fond anticipations? On the contrary, it was the bright and pretty side of the picture that was presented.

Those of us who live in New York, and who have steadily on hand a hard fight for purity in municipal affairs, may be forgiven if we view askance any movement to add to the responsibilities and evil opportunities of city officials; and also if we doubt a little as to the real good that can come from meetings of the League, such as that at Detroit, well intentioned as many of its members are, beyond question. But even in Detroit, while the glamor of the occasion is over the scene we trace the same lurking scepticism, as expressed and summed up by the Detroit "Tribune" in the following paragraph: "The 'Tribune' trusts the League will not overlook a solution for that most important municipal problem, 'What shall we do with the workers between elections?'"

German Central Station Statistics.

JUDGING from the reliable data collected and published by the "Elektrotechnische Zeitschrift" the condition of the electrical industry in Germany continues most gratifying and encouraging. The figures given by our contemporary only relate to central stations supplying current for light and power to entire cities, towns or large sections of them, excluding private installations and those supplying electric railroads. The statistics bring the state of the industry up to the first of March, 1898, and show that over 100 new stations have begun operation during the past year, the number of stations increasing from 265 to 375, besides 78 stations are in course of construction, and the prospects for the coming year are indicative of a large increase. The continuous current still holds its own in first place, being distributed by 81 per cent. of all stations, while their output is only 59 per cent. of the entire station output. Their number has increased 48.5 per cent. over 1897; 89 per cent. of these stations have battery accessories whose output amounts to about 31 per cent. of the total; 29 stations employ the alternating (single phase) current, an increase of only 11.5 per cent. over 1897. There is, however, a 42.5 per cent. increase of polyphase (Drehstrom) stations and their total number now amounts to 23. Their output has increased 84.7 per cent. over 1897; 18 stations generate both polyphase and continuous currents, and their output has increased 164.4 per cent. over the previous year. Single phase alternating and continuous currents are generated in 5 stations, an increase of 66.7 over 1897, while their output has been increased 6.88 per cent.

Germany, possessing but little available water power, has to depend almost entirely on steam as a motive power for central stations, and the statistics therefore show that of all the stations 84 per cent. are operated by steam, 14 per cent. by water and 2 per cent. by water and steam combined. However, it should be

noted that only very small plants, generating less than 100 k. w. use water for their motive power, only 8 stations having an output larger than that. About 4 per cent. of all stations use gas as a motive power, and several use both gas and water.

Another table gives a comparison of the works according to their output, and it is shown that 61.6 per cent., or over half of all stations, have an output of less than 100 k. w., about 27 per cent. between 101 and 500 k. w., 20 stations between 501 and 1,000, 14 from 1,001 to 2,000, 8 from 2,001 to 5,000, and 3 a total output of more than 5,000 k. w. Nearly all stations have been materially increased during the past year.

Another feature of great interest brought out is the increase of the stationary motor load, namely 64.4 per cent. over 1897. The incandescent lamp load increased 39.3 per cent. and the arc lamps 30.2 per cent.

The total output of the stations is equal to 2,401,067 lamp equivalents equal to a capacity of 111,539 k. w. The motor load is 28.9 per cent. of the total load of the stations which is a remarkably high figure.

Another table shows the rapid increase of the electricity supply works during the past ten years, the number having increased from 59 built in 1896 to 90 built in 1897. To show that there need be no fear of a sudden halt in this rapid increase, it is pointed out that there are a large number of important and well-populated cities without a central station, and that these will soon demand it for their every-day comforts and conveniences. Another table is added to show the distribution of the electric light in several large German cities, giving the number of lamps per 1,000 people in cities with over 100,000 inhabitants. Berlin, for example, with a population of 1,677,304, has 217,612 incandescents, 130 for each 1,000 inhabitants, and 298,392 arcs, or a total of 178 incandescent lamp equivalents for each 1,000 inhabitants, while for Bremen with a population of 141,894 this figure reaches a maximum in 338, and in Dortmund, with a population of 111,232, it is a minimum in 57. From these figures it will be seen that there exists a most wholesome condition in the German central station field and one which cannot but have a most beneficial effect on the entire electrical industry in that country.

Recent Progress in Electrolytic Operations.

ON other pages we give a detailed description of the Tommasi electrolyser, a simple and apparently efficient apparatus for the extraction, separation and refining of metals. In view of the rapid strides made within recent years in electro-metallurgical operations and the saving effected thereby, the process described by Mr. Tommasi is full of promise, as the inventor has carefully studied the difficulties inherent in the present methods and the necessary conditions to be fulfilled for the most economical working, and has constructed his apparatus accordingly. It is universal in its application for the electrolytic refining of metals, and the advantages claimed for it are (1) the doing away with polarization, (2) the removal of the metal as soon as it is deposited, (3) equal density of the liquid in all parts of the electrolyser, due to the fact that it is continuously in motion. Mr. Tommasi also shows the application of the apparatus to the electrolytic desilverization of argentiferous lead, pointing out its several essential advantages over existing methods, and he gives the results of a series of experiments made to determine the dimensions of a plant for working his process. His figures show a decided gain from using the Tommasi apparatus, the profit being even more apparent from his figures in regard to a plant for the production of spongy lead used for accumulator purposes. It appears from these calculations as if Mr. Tommasi has materially advanced the state of the art, especially in the economical extraction and refining of the heavier metals.

More progress, however, has been made in recent years in the electrolytic production of the lighter metals, principally among which are magnesium and aluminum. Metallic sodium has also recently been obtained by electrical means. Another problem of great interest is the electrolysis of alkali-chlorides in water solution, such as the chlorides of sodium and potassium. While considerable progress has been made in this direction, a number of difficulties have presented themselves which are being slowly overcome by improved appliances and methods. Among these may be mentioned the secondary reactions taking place, the formation of the caustic alkali and its reduction and

the inability of the carbon electrodes to withstand the action of the chlorine for a considerable time.

The production of iodoform by electrolysis, which has also been accomplished of late, has become a most promising industry, and shows the possibilities of the electric current in the domain of organic chemistry.

Protecting Well-Behaved Lighting Corporations.

A RECENT decision by a committee of the British House of Commons is being regarded with considerable pleasure by our friends in England and is worthy of note from its bearing on questions here. The particular instance was that of Marylebone, a large and rich section of London, where the Metropolitan Co. has been at work for some ten years past, under a "provisional order," as it is called, which required the lapse of forty-two years before the vestry could purchase the plant. But the company, having worked up its business in good shape, the vestry thought it would be nice to take a hand itself, and thereupon applied for "concurrent powers," just as some private companies have done in places where municipalities have plants. When the question came before the House of Commons the Association of Municipal Corporations supported the vestry, and it was referred favorably to the committee, where the real tug came, evidence being taken for and against. On one side it was urged that local authorities should be able to do electric lighting even with a company already working in the district. On the other side, the doctrine of "peaceable possession the reward of good behavior" was urged, aside from contract rights, together with the argument that any such disturbance of the security of tenure would scare capital and retard the industry. As we have noted, the committee has protected the company, at the same time protecting against any company a local authority that has already by original order or purchase engaged in the business.

This decision, it seems almost needless to add, has given general satisfaction, and one result has been a healthy rise in electrical securities. Many lighting companies here that have been violently assaulted and had their property undergo virtual confiscation might well wish for a similar treatment. The English ideal of equity and justice shines through the transaction just as it does in the work done by the Massachusetts Lighting Commission, endowed by the State with powers which enable it thus to arbitrate in such matters.

"Electric Belts."

THE exact incidence of some of the new war revenue taxes is still uncertain. We have made note of the struggle over the one-cent tax on all telegrams and the success thus far of the telegraph companies in leaving it for the customer to pay. But there are some unexpected points in regard to other items, and we are very sorry to note one decision falling within the proprietary schedules of the law, and that is, that "electric belts" are held to be mechanical appliances and not taxable under Schedule B as medicinal preparations. Electricians will hardly find fault with the dictum that an electric belt is not a "medicinal preparation," but they will be at a loss to understand why it passes muster as a "mechanical appliance." It does not hold up the trousers of its wearer, neither does it pull down his shirt or vest. It is true that it is not held on magnetically, but that is also true of collars and socks, and they are not looked upon as in any sense mechanical appliances. If an "electric belt" were held capable of hitching a steam engine to a dynamo and thus helping to generate current the propriety of the term would commend itself, but we have never seen an "electric belt" used in that way. Perhaps our readers have, and will be better able than ourselves to penetrate the mental mysteries of the fiscal expert who looks on electric belts in the light of suspenders. We accept the dictum that "the first absolute pre-requisite to the imposition of the tax is that the article should be medicinal in its character," for that is certainly what the "electric belt" is not. But why should mechanical be the alternative or antithesis to medicinal? Why not say outright that the belts are fakes?

THE Volunteer Engineer Corps went on board the fine transport Chester for Porto Rico on Saturday last, mustering nearly 1,100 strong. The ship was visited by many persons while lying down the bay.

Detroit Convention of the League of American Municipalities.

THE League of American Municipalities held its second convention last week at Detroit, Mich., and had a large attendance of delegates and visitors, numbering probably 1,000. The League was heartily welcomed by Governor Pingree and Mayor Maybury. In his opening address President John Mac-Vicar, of Des Moines, Ia., said:

"It is the work of the League, so far as it embodies and represents the public determination to have good city government in this country, to study the question before it in a broad way. American cities must be made wholesome in every sense of the word. They must, if such a thing be possible, be made to conserve and not consume the energies they draw from the country. They must have no slums to pollute the currents of their own lives and the life of the nation. The garbage question, the tenement question, the water question, the franchise question, the question of parks, public baths, playgrounds and other means and instruments of public health and recreation, must be studied in their larger relation to the preservation of the life and health of our great republic.

"We are at an early stage of the movement; the country has but recently awakened to the need of it. Some of the matters to which I have alluded are for future generations to adjust. At the threshold of the agitation we are most concerned with the vital issue of the sovereignty of cities. It seems necessary as a preliminary measure to eliminate from our cities the private ownership of franchises for the monopolized use of the streets. The public must own and operate all plants for the supplying of light and water. Probably it should extend its powers so as to take in street railways, heating plants, telephones and other means of intramural communication. At all events, there must be an end to the controlling and corrupting of our city governments by those interested in the manipulation of public comfort, even if the last vestige of private ownership in them shall be uprooted.

"To those good but misguided people who, without having perhaps devoted time to an examination of the subject and are therefore disposed to oppose municipal ownership and control of the natural utilities represented by water, gas, street railway and electric lighting plants, I would put this pertinent question: Whence the fertile source of those corrupting influences which too often debauch city councils and as often lead State legislatures, and perhaps sometimes our national Congress, astray? Did they ever hear of a city or State tempting a public official with bribery to betray the interests he has sworn to protect? Surely not. The potent cause to which public officials sometimes yield must be sought for elsewhere. Are not the colossal opportunities offered through the medium of exclusive privileges granted by city councils and legislatures the very foundation of this evil? I think you will agree with me that they are. Therefore, if these valuable franchises, these splendid privileges, were reserved to the cities, would not this source of corruption which has caused legislative bodies to become a byword among the people cease to exist?

"Such a change involves the necessity of civil service reform. I am aware that our western metropolis at a recent political convention declared for municipal ownership of public utilities and for the repeal of the civil service laws. To my mind it would be suicidal to enlarge the function of municipalities without providing for the thorough application of the merit system in appointments, promotions and removals. We who believe in municipal reform are in the paradoxical position of proclaiming that our cities are doing badly that which they are doing, yet urging that they assume new duties. But the logic of our contention is better than it seems. Burden develops responsibility. There is a reserve of patriotism and capacity of self government in our citizenship to which we are not afraid to appeal. Nothing could do more to bring out the latent virtue of the indifferent citizen than freighting the ship of state, already, as he fears, overloaded, with still dearer interests. I

am not afraid to startle our money-making voters by producing a situation which will alarm them into a state of perpetual political vigilance. They need to be alarmed. Arouse them to the seriousness of the prevailing condition and the spasmodic energy which now cleans the Augean stables of municipal corruption once in ten or fifteen years will be harnessed by unavoidable necessity for regular activity. Public sentiment would from sheer necessity and constant contact with these public servants, whose functions would be to supply them with street transportation, light and water, exert an influence that would not be satisfied excepting with the best service possible. Every citizen would be interested in securing the greatest efficiency in the public service, and in a very short time demands would be made by a quickened and enlightened popular sentiment for the enactment of a strict civil service law. So long as the corporate interests operate these public utilities for private gain just so long will we have uncompromising opposition to civil service and good city government. Remove first the incentive to this opposition, which to my mind can be accomplished by removing our public franchises from the public mart, and a new era will dawn in which the best citizenship will be the dominant force in municipal government.

"These two reforms (municipal ownership and civil service) accomplished, there will be less to prevent the peaceful evolution of good government in municipalities. I place them first because they are logically first, and will open the way to others. But as I appealed a few moments ago against the too concrete treatment of these questions, I must warn you against being too theoretical and uncompromising in handling them. We should not insist that progress and improvement come to us in a certain order. Let us rather rejoice that the leaven of municipal reform is everywhere at work, rousing the public to a new sense of obligation of citizenship. If better city government does not come in the order we deem logical and proper, we should welcome it in all its aspects and contribute in every possible way to the advancement of the cause."

Secretary B. F. Gilkison reported the present membership of the League at 71 cities. He alleged that corporations had waged war against the League, with possibly injurious effect.

A number of topics were discussed during the convention, including the operation of municipal lighting plants, upon which Prof. Bemis spoke, without giving any new data.

On Friday, the morning session was devoted to an active discussion of the "Municipal Ownership of Public Industries."

T. S. Murray, mayor of Denver, spoke on "Remuneration to cities for franchises rights in, over and under public streets and alleys. What remuneration, if any, should be exacted from light, water, street railway, telephone and subway corporations, and how should it be collected?"

He declared the proper management of the government of municipalities to be one of the serious questions of the day. The population of the large cities is annually increasing much more rapidly than that of the agricultural communities, the tendency of population being to concentrate in the cities. In 1790 only 3 per cent. of the people of the United States resided in cities, but in 1890 this had increased to nearly 28 per cent., while it is now estimated at one-third the entire population. This rapid increase of urban population is constantly raising new questions of municipal government that are of the first importance to every resident and property holder of a city, for he comes in contact with the city government a hundred times to the State or national government once.

A constantly increasing tax rate is not received with favor by the taxpayer, but at the same time the average citizen clamors for improvement in every department of the public service. Attention is then given to the possibilities of increasing the revenues of a city without placing unbearable burdens upon real estate and improvements, and the conclusion of such contemplation is that profligacy has ruled in the bestowal of valuable franchises.

Then it is that the citizen learns that the franchises so freely given by willing councils and mayors to great corporations, covering the great public utilities of the municipality, have been turned in as a valuable item of property among the assets of the corporations and a large amount of money borrowed thereon. The conclusion is inevitable that if a franchise becomes a thing of value as soon as it is received by a corporation, it is of value when asked for at the hands of the representatives of the people.

It therefore follows that if a sum somewhat commensurate with the value of these franchises and privileges be received for them, a source of revenue has been established that will relieve the burdens of the taxpayer.

The streets and alleys of a city are the heritage of the people and should never be given away for the aggrandizement of any private corporation. Mayors and councils are merely trustees for the management of the business of a municipality, but they frequently act as if they themselves were the owners in fee simple to the public highways and had the right to dispose of them at will, giving away the valuable possessions of the people without any consideration of the rights of their immediate constituents or of the succeeding generations.

All the great public utilities of our municipalities should be retained in the hands of and under the management of the people themselves, and no private corporation in any American city should have any more right to control the water we drink than the air we breathe.

Many of the public utilities are and must be in the nature of monopolies. There can be no true competition in the furnishing of water, gas, electric lights, telephones, etc., and tramways are entering the same category. They are no longer luxuries, but actual necessities. The time should speedily come when all the great public utilities of our American municipalities will be owned and operated by the people themselves through the business administration of their municipal government.

Until this time comes, what remuneration should be paid for these great rights and privileges which are sought for so greedily in every portion of our land? In the construction of a street railway the city puts in the franchise and the right of way, the corporation the tracks, cars, power and machinery. It is a partnership, but the rights of the city partner are thereafter ignored. The city is not allowed any voice in the management of the road nor any consideration for its share of the partnership property.

For the franchise the city should receive the percentage of the gross receipts; for the right of way, the same rate of interest as the bondholders receive, the value of the right being determined by the value of the abutting land.

There was some little struggle over the secretaryship, at the annual election of officers, Mr. B. F. Gillison being accused of violating the constitution, as to the receiving and paying out of League moneys. He was, however, elected by 29 votes, against 13 cast for J. H. Mahoney, president of the Indianapolis common council. Mayor Black, of Columbus, O., was chosen president; Mayor Taggart, of Indianapolis, was chosen treasurer, but resigned in favor of Mayor Taylor, of Bridgeport. The trustees elected were J. MacVicar, of Des Moines; J. H. Smythe, of Charleston, S. C., and C. S. Ashley, of New Bedford, Mass. The next place of annual meeting will be Syracuse, N. Y.

The Decreasing Demand for X-Ray Apparatus.

BY W. J. CLARKE.

DURING the first few months following the announcement of the discovery of the X-rays by Prof. Röntgen, it was found almost impossible to supply the enormous demand for induction coils and Crookes tubes. The coil makers of this country had a new problem to solve. While for years some of them had been manufacturing coils which were intended to be used only for a few moments in experimental work, none of them had ever dreamed of turning out coils that would withstand the severe work incidental to the production of the X-ray. Consequently it was but natural that many of the coils sold during the above mentioned period were found to be defective in many ways, but as usual in such cases the American inventor stepped to the front, and at the present day coils for X-ray work are being sold by several firms in this country, which we feel safe in saying are far superior to those manufactured by foreign firms who have given their entire attention to this work for many years.

The earlier form of Crookes tube was also defective in many

ways, it frequently happening that the vacuum in these tubes would rise during an hour or two's use to such an extent that the coil would spark around the tube, and it would have to be re-exhausted before it was possible to use it again. In order to overcome this, tubes having an adjustable vacuum have been designed by several manufacturers, and for all ordinary work some of these tubes have proved themselves to be all that is to be desired. It is found, however, that they do not possess the powerful penetrating power of some tubes that are not provided with the adjustable vacuum arrangement, and consequently, a surgeon, in order to be properly equipped, should possess an adjustable vacuum tube for all ordinary examinations of the extremities, but for examining the denser portions of the body it is necessary that he should have another style of tube not provided with the adjustable vacuum device, and it is also necessary that this tube be worked up to a point of very high vacuum in order to secure the best results. Unfortunately, these results last such a very short time that it is necessary to be provided with a number of these tubes, especially as it is found that even when they are re-exhausted with the greatest care they never have the same penetrating power as when new.

When the discovery was first announced nearly every surgeon of prominence in the country made up his mind that it was absolutely necessary that he should have a complete outfit, but as it was some months before the manufacturers were able to produce reliable apparatus, a great many surgeons were more than discouraged with the results obtained from their purchases, and in addition to this, the price of the apparatus was held at an extremely high figure so as to place it beyond the reach of nearly all surgeons except those who had the good fortune to enjoy a lucrative city practice.

It has been my privilege to be brought in contact with nearly all of the manufacturers of X-ray apparatus in the country, and each one has unhesitatingly stated that the business has greatly fallen off during the past year, until at present but very few outfits are being sold. Now I think that this condition of affairs can be attributed to two causes. The first of these is the fact that although the apparatus now being sold in this country is far superior to that manufactured abroad, it is still much too complicated for the average physician or surgeon to handle intelligently. As it has become pretty generally known among the profession that X-ray apparatus gives considerable trouble, it is but natural that they should defer purchasing as long as they possibly can, or until such time as some more easily operated apparatus is devised. The second reason why I think trade in this line is falling off very much is on account of the fact that the best apparatus is being manufactured by a few firms only, and they naturally, knowing that they have the best, are asking what seems to be an abnormally high figure for their output.

In the hands of an expert, almost any X-ray apparatus will give good service, as witnessed by the fact that at the recent Electrical Exhibition in the Madison Square Garden, the Exhibition Company's outfit was in continuous operation for nearly eight hours each day for over three weeks, and during that time not a single breakdown occurred, and only two tubes were used. At the same time, it is likely that the same outfit placed in the hands of a physician or surgeon would give considerable trouble even after a few hours' use. It seems clear to me, however, that in order to get the physicians interested again, and to push the X-ray business to the front, it is necessary to devise an outfit that will be compact, reliable, easily handled by a novice and sold at a reasonably low price. I can see no reason why an outfit of this kind cannot be manufactured and sold at the price of \$100, which would bring it within reach of the entire profession, and I feel that until this is accomplished the trade in X-ray apparatus will remain at its present low ebb.

A Possible X-Ray Lightning Effect.

WE have received from Dr. G. J. Mack, of Waterloo, Iowa, a photograph of a lightning flash presenting a curious feature worthy of notice. At the lower left hand corner appears a 2 x 2 inch wooden clothes reel arm projecting into the picture. Two streaks of lightning seem to have passed between the wooden arm and the camera; at any rate, the parts of the lightning streaks which ordinarily would be hidden by the obstructing clothes reel show up directly through the wood, as if the latter had an X-ray effect. We doubt it.

Polarisation of Röntgen Rays.

This is one of the "X-ray Myths" exposed by Dr. S. P. Thompson. L. Graetz (Wied. Ann.) had the happy idea of endeavoring to produce X-rays readily polarized by letting the cathode rays impinge upon crystals. According to Sohncke, all fluorescing crystals send out polarized light. Graetz used calcspar, tourmaline, andalusite and dischroite. Now, if the Röntgen rays proceeding from these crystals were polarized, a single tourmaline crystal outside could be used as analyzer. The tourmaline tongs would be even more effective. Positive results appeared to be obtained on the screen, but photographs showed no trace of polarization, nor could it be detected with a Nicol. Further observations showed the apparently positive results to be due to inequalities on the fluorescent screen used for observation. It appears, then, that even with this most powerful means polarized X-rays cannot be produced.

Testing the Purity of Coal by Means of X-Rays.

ACCORDING to "Engineering" Mr. M. H. Couriot recently suggested a novel use for the X-rays in a note communicated to the Paris Academie des Sciences. Professor Röntgen's discovery has already proved of great service in surgery, but Mr. Couriot suggests that the rays may prove as efficient in showing the intimate structure of siliceous skeleton of our coals as they are in defining the calcareous skeletons of animals. He states that by means of a powerful Crookes tube and a fluorescent screen, it is easy to determine the purity of a fuel. Carbon in all its forms is exceedingly transparent to the rays, whilst silica and silicates are opaque; and on placing a lump of coal between the tube and the screen, all the intimate details of the slag and clinker forming portions of the fuel at once appear. Mr. Couriot has tested in this way anthracite, coal, lignite, peat, coke and block fuel. The finest particles of silicate, though quite invisible to the eye, show up at once on the screen as dark spots or bands upon a bright ground. The differences in the quality of a series of coals can be traced step by step, showing at once the variations in the purity of the fuel. The conglomerate structure of block fuel is clearly exhibited, whilst with coke the particles of iron sulphide are indicated by black spots on the fluorescent image. Carbon is so transparent that it is unnecessary that the samples should be regular blocks, as rough lumps, the sides of which usually follow the natural planes of cleavage of the coal, serve perfectly well. Mr. Couriot has taken radiographs with specimens $1\frac{1}{2}$ in. to 2 in. thick, the coil having a spark 10 in. long, and the exposure being five minutes.

Preventing Collisions At Sea.

IT was with very great interest that I read the article of Mr. Hermann Herberts in the last issue of the Engineer, entitled "Means for Detecting the Presence of a Ship or Iceberg," and while the arrangement suggested by Mr. Herberts is certainly extremely ingenious and well worked out, I am, nevertheless, of opinion that the use of wireless telegraphy apparatus is the only successful way in which collisions at sea can be avoided.

Were it made compulsory for every seagoing vessel to be equipped with the necessary outfit, the demand for apparatus would be so great that its cost would be largely reduced, so that a ship could be fully equipped for a comparatively very small amount.

The arrangement of the apparatus would be such that when two ships approached each other a large vibrating gong would ring in each, and the transmitter could be so adjusted that this signal would take place at a distance of from one to ten miles, according to what was decided to be the most suitable distance at which such signals should be given.

I am of opinion that but very few people are aware as yet of the state of perfection to which wireless telegraphy apparatus has been brought in this country and feel quite sure that if the public were convinced of its reliability it would be but a very

short time until its adoption for signaling on shipboard would be compulsory.

W. J. CLARKE,

General Manager U. S. Electrical Supply Co.

New York City, Aug. 3, 1898.

Shunt Method of Motor Control.

I AM reminded by the article and editorial on the Henry "Regenerative" Control in your July 21st issue of the Biblical promise that we shall all be born again.

As a contribution to history, it is in order to make reference to the following:

1st. Paper read in Boston at the meeting of the Society of Arts in December, 1885, setting forth somewhat fully the shunt method of operating railway motors, and the saving to be effected by returning current to the line by systems afterwards (about ten years ago) patented.

2d. Description of the experiments carried on for months on the Thirty-fourth street branch of the Manhattan Elevated Railroad, in the winter of 1886-7, in which these methods were put in practical test, and which tests were fully described in Martin and Wetzler's work on Electric Motors.

3d. The practice which has obtained for a number of years in certain classes of stationary and elevator work.

FRANK J. SPRAGUE,

Vice-President and Technical Director Sprague Elec. Co.

New York, August 1, 1898.

MR. HERMANN HERBERTS, of Newark, N. J., whose method of detecting the approach of a ship or iceberg at sea was illustrated in our columns last week, has been very much encouraged by a number of letters he has received on the subject. He is taking the matter up in real earnest, and has proposed the appointment of an international commission, whose duty it shall be to investigate and report on the various methods proposed for insuring the safety of vessels during a fog.

The American Street Railway Association.

The following is a list of the topics and authors for the annual meeting in September of the above association:

"Maintenance and Equipment of Electric Cars for Street Railways," by M. S. Hopkins, electrician, Columbus Street Railway Co., Columbus, O.; "To What Extent Should Railway Companies Engage in the Amusement Business," by W. S. Holmes, general manager Metropolitan Street Railway Co., Kansas City, Mo.; "The Carrying of United States Mail Matter on Street Railways," by W. S. Dimmock, general superintendent, Omaha and Council Bluffs Railway and Bridge Co., Council Bluffs, Ia.; "The Comparative Earnings and Economy of Operation Between Single and Double Truck Cars for City Use," by Richard McCulloch, electrical engineer, Cass Avenue and Citizens' Railway Co., St. Louis, Mo.; "Inspection and Testing of Motors and Car Equipments by Street Railway Companies," by Frederick H. Perkins, electrical engineer, Toledo Traction Co., Toledo, O.; "Cost of Electric Power for Street Railways at Switchboard; Both Steam and Water," by R. W. Conant, electrical engineer, Boston Elevated Railway Co., Boston, Mass.

Ohio Electric Light Association.

This excellent association holds its annual meeting at the West House, Sandusky, O., August 18 and 19. Secretary Scovil reports a good programme with several useful papers by well-known engineers and lighting managers; and the Sandusky Lighting Co. has laid out a choice programme of entertainment.

SYRACUSE, N. Y. The Merchants' Association of New York advocates special attention being paid to the annual State Fair at Syracuse, given by the New York State Agricultural Society, of which Hon. B. F. Tracy, ex-Secretary of the Navy, is president. The fair is held the last three days in August, and the first three in September. A good electrical exhibit is expected.

MISCELLANEOUS

Magnetic Clutch For Heavy Station Work.

IN the course of a very interesting paper, read at the recent Omaha meeting of the A. I. E. E., on a modern central station, namely that of the Imperial Electric Light, Heat and Power Company, of St. Louis, Mo., Mr. George A. Damon described the "Arnold System" of connecting engines and generators¹, which had been adopted in this plant. This system of power station design is well known, but as applied in this instance it embodied several novel features, not the least interesting of which is the coupling device or clutch, described below, it being the first magnetic clutch applied upon a large scale to power station work.

The figure shows a cross-section of the clutch. One part, B, is bolted to the engine flange, N. A corresponding part, D, is bolted to the generator quill, H, and this part carries an annular armature, A. Radial arms F, keyed to the solid shaft G, carry an interior armature C. Each coupling is provided with five circular coils of magnet wire, O, P, R and S. These coils are electrically connected to contact rings J, K and L, carried on insulating bushings bolted to the hubs of the clutch.

DETAIL OF MAGNETIC CLUTCH.

Stationary brushes which are connected through a system of switches to the storage battery 'bus-bars make it possible to send a current around any coil. The parts of the clutch containing the coils are made of cast-steel of high permeability so that when a current is sent around any coil, the surrounding metal becomes a magnet and the armature facing the coil is immediately magnetically attracted. The two surfaces of the clutch parts being held in contact by a pressure of at least 80 pounds per square inch, it becomes possible to transmit power from one to the other. Thus to connect engine shaft N to generator quill H, a current is sent through coil O in that part of the clutch B attached to the engine shaft. Armature A which is attached by means of strong studs to that part of the class B which is securely bolted to the generator quill, is immediately attracted and overcoming the small resistance of the spring G, the two parts become firmly attached to each other, making it possible to run the generator from the engine. If it is desired to revolve the interior shaft by means of the engine, the current is sent through coils P and Q in parallel, attracting armature C, while if the solid shaft is being turned by the other engine and it is desired to connect the shaft to the generator quill, then coils R and S are energized and the armature C

is attracted in the other direction. The circuits to these coils are all controlled by means of switches on the main switch-board. These switches are so arranged that when the circuit of any coil is broken, the discharge of the extra current is taken up through a carbon resistance, and the insulation of the coil is therefore protected from the liability to puncture. When the current in any coil is discontinued, spiral springs have been provided to overcome the residual magnetism and bring the armature back to its original position.

If both parts of the clutch which are to be attached are stationary, the connection becomes an easy matter, but if one part is revolving, it becomes necessary to put the other part in motion before the current is sent through the coils. This is accomplished by starting the dynamos as motors and bringing them up to speed before closing the magnet coil switch. For this purpose, regular starting boxes have been installed, one for the boosters and the other for the generators, so that any machine may be thrown into or out of service directly from the switchboard. The result of the whole arrangement is, that a number of combinations between the engines and the generators become possible. Under all normal running conditions, the centre engine will run its two adjacent generators and the outside engines will operate the end generators. Each booster may be run when necessary, from either of two engines. The entire line of machinery may be connected together, so that all the engines and generators operate in unison as one large unit, the speeding attachment on the engines making it possible to operate them satisfactorily in this manner.

In case of accident to any generator that particular machine may be stopped without stopping its corresponding engine, and the electrical load will be immediately taken up by the other generators, but without overloading the engines. In case of accident to any engine, the ability of the other engines to carry an overload of 100 per cent. may be taken advantage of, if necessary, without overloading any of the generators. Thus the centre engine is capable of carrying all four of the generators fully loaded while the smaller end engines can operate two of the generators, if necessary, in case of a break down of the larger engine. The plant may, therefore, operate at period of maximum load, at its full rated capacity, depending entirely upon the advantages of the system of arrangement for a reserve in case of a breakdown to any part of the equipment.

Concentration of Power by Electric Transmission at Taunton, Mass., Tack Works.

ONE of the most forcible of the advantages of electrical transmission of power is that this method often makes it possible to combine two or more steam plants into one, greatly diminishing the cost of labor and supplies. Such an advantage appeals especially to the mill owner, who may operate shafting in several buildings and departments by separate sources of power. A conspicuous example of a wasteful arrangement is in the works of one of the largest locomotive shops of the country, where part of the plant is operated by water power, part by steam power, and part by compressed air, the latter necessitating an extra engine and compressor.

Electric transmission, and notably the polyphase system, as developed by the Westinghouse Company, has made it possible to centralize the power in such shops. When Lieut. L. O. Garrett took charge of the affairs of the Atlas Tack Co., of Taunton, Mass., as manager, he instituted a thorough investigation as to the power required for the various classes of tack making machinery under normal conditions. The mills of this company at Taunton are three in number, located from 800 to 1,200 feet apart, and were until recently operated by three separate steam plants, with the accompanying wastefulness incident to small units. It was found that owing to variations in the amount of power required from day to day for the different classes of work, the duty of the three steam plants could be easily performed by a single steam plant of two-thirds their united capacity.

¹Electrical Engineer, May 16, 1894, and May 27, 1896.

So large a saving in coal and labor as was expected from this arrangement induced Lieut. Garrett to engage the services of Mr. T. W. Sprague, of Boston, Mass., to investigate jointly with him the various systems of transmission. The parties interested inspected personally a number of the principal polyphase plants among the New England mills, and finally selected the Westinghouse three-phase system, 3,600 alternations, as best adapted to the work of the Atlas Tack Co. This system, in connection

FIG. 1.—150 K. W. WESTINGHOUSE GENERATOR.

with the Tesla "Type C" motors, made by the Westinghouse Electric and Manufacturing Co., has attained marked success in every instance in which a plant has adopted it, and the alternate current motor, though developed later than the direct current motor, has been favorably received in all such installations.

The Atlas Tack Co. are to use a 150-kilowatt Westinghouse generator, shown in Fig. 1, which will operate 9 Tesla induction motors of the above type, shown in Fig. 2, ranging from 3 to 50 horse power, in the various mills. The gas lighting system of the mills will be replaced by about 1,000 incandescent lights.

The company instituting these changes is one of the most progressive of manufacturing concerns, employing over 500 men,

FIG. 2.—TESLA INDUCTION MOTOR.

and making some 10,000 brands of tacks, rivets, etc. Considerably over 50 per cent. of all the tacks and rivets made in the United States are produced at their shops, and their electrical equipment will be watched with interest, and no doubt imitated by many other concerns of the kind.

The adaptability of the "Type C" motor, as made by the

Westinghouse company, to so many varied fields of usefulness, has surprised many, who have possibly been prejudiced against the alternating current motor; but the cause of their surprise constitutes one of the strongest proofs of the reliability of this new Westinghouse product.

QUEBEC, CANADA. Plans are on foot for the utilization of the Shawinigan Falls, in the Province of Quebec, near the city of Three Rivers. There is a fall of 165 feet, and it is said 200,000 h. p. can be developed. A charter has been granted to the Shawinigan Water and Power Co.

REPORTS OF COMPANIES

Bell Telephone Output.

The American Bell Telephone Co. made a good addition to total instruments outstanding in licensees' hands under rental for the month ended July 20, as the following figures show:

July—	1898.	1897.	1896.	1895.
Gross	21,551	15,859	12,584	13,837
Returned	10,011	7,241	10,490	7,513
Net output	11,540	8,618	2,094	6,324
Dec. 21 to July 20—				
Gross	187,884	127,778	126,678	98,896
Returned	83,306	51,847	53,667	47,121
Net output	104,578	75,931	73,011	51,775
Total outstanding				
July 20	1,023,699	848,558	747,987	625,450

Wrought Iron Bridge Co., Canton, Ohio.

WHILE the name of this company might indicate that they only deal in bridge work, their products are by no means confined to steel structures of this class, but embrace building material, viaducts and roof trusses, the latter being especially adapted to the requirements of car houses and power and lighting stations. The products also embrace transfer tables, and turntables for steam cars and locomotives. The works occupy a tract of twelve acres situated in the southwest part of Canton, and connected by switch tracks with a number of railroads, giving excellent receiving and shipping facilities. The works employ about one hundred men.

A distinctive feature of the plant is the employment of electric motors for the operation of the individual tools and for this purpose twenty-one motors are employed, ranging from three to twenty horse power. These are supported by the roof members, and the power is transmitted to the tools by vertical belts. The cost for maintaining the motor equipment together with the material for repairs is said to be less than \$100 per year—a degree of economy that could not possibly be met with shafting and the ordinary methods of power transmission. The material, consisting of steel bars of all dimensions, is delivered on steam cars to the storage yard or stock house, which is a separate structure, and from which by means of narrow gauge trucks the material is conveyed to the structural shaft according to the demands. The whole floor and the main shop is provided with skids having metal plates on the top, and these are arranged systematically in rows across the building with the tools, including punches, shears and drills, conveniently located and arranged in consecutive line from east to west across the shop. There are also rolls and pulleys on which the material is readily moved to or from the tools. The material first enters the shop on the north track and is unloaded upon the adjacent skids, where it is laid off from templates and marked for punches

and shears, then from these machines to straightening machinery or curving rolls, then to assembling skids, and from there to the reaming tools. These tools are of novel design and are known as the Ross reamer. These are arranged in a straight row across the shop above the line of skids, there being from fifteen to twenty separate tools. These are each operated by means of a vertical shaft about 18 feet in length, which is driven by beveled gear from a main horizontal overhead shaft. The vertical shaft is telescoped for a part of its distance, a square shaft being let into the hollow of the round shaft and this shaft is provided with two universal joints, one near the top end and one other near the tool. By means of levers and the clutch the shaft is started and the reaming tool which has a range of several feet in any direction and at any angle is inserted in the rivet holes and quickly reams them to the proper size, all punched holes being thus reamed. The material next goes to a riveting machine, and for this purpose four pneumatic reamers of different capacity are employed. These are all in one line, and are manipulated by being suspended by hand hoists from an overhead trolley car, giving a large range for action and providing for quick work. For heating the rivets four open hearth furnaces, in which oil is employed for fuel, are located

and diagonals are forged by hand. The wood working machinery and tools for making templates and patterns occupy a room on the north as described above. The steam equipment occupies a brick building 30 by 50 feet adjoining the east side of the main structure. The boiler is of the Hazleton type and is equipped with Murphy stokers. A Russell engine with cylinders 13 x 20 inches and rated at 100 horse power furnishes power for driving three generators, one for power and the other two for arc and incandescent lighting. It also drives a 10 x 12 inch two-stage Norwalk air compressor for operating the riveting machines in which 100 pounds of pressure is employed. The building is heated by the Sturtevant hot air system, there being a chamber containing coils of pipe over which the air is blown by means of a fan, whence it is led about the structure through large galvanized iron pipes supported in the roof members, from which numerous branch pipes deliver the blast to all parts of the building.

The main office and draughting department occupy spacious quarters in a separate building, together with suitable offices for the clerical department. Here are found the usual equipments of office, fireproof vaults, and appliances for conducting the accounting and draughting departments. The affairs of the

FACTORY OF THE WROUGHT IRON BRIDGE CO., CANTON, OHIO.

in close proximity to the pneumatic riveters and near the middle of the floor. The hot rivets are passed through the machines by boys and are headed by the riveters about as fast as one can count. Next comes planing mills and drills for special work where some finish is required on parts that are not readily accessible, and for this more or less hand riveting is required. There are also two single-headed milling machines for column work, by means of which the top or base of the column is dressed to any angle. The largest of these tools is a disc about three feet in diameter while the cutting tools are inserted in the face. This is mounted on a swiveled base and there is an idler for supporting columns of any length. The material while undergoing these various operations has passed in a zig-zag course from north to south, arriving in a finished condition ready for painting, when it is loaded directly on the cars for transportation or is directed to the storage for finished material. For shipping, the main switch track enters the shop on the south side on tracks depressed four feet below the shop floor, so that the operation of painting as well as the loading of cars can be carried on regardless of the weather. The bridge work is not confined to truss and girder structures entirely, but large sheet metal tubing is also constructed for bridge piers, designed to be filled with concrete when in place. In the forging and blacksmith department there are four forges, one furnace, one large steam hammer, and a bolt and rivet making machine. There are also thread cutters for cutting rods of any size. Here the loops and links in the ends of long rods designed for lower

company are conducted by the following officers: F. M. Wyant, treasurer and general manager; E. J. Zander, chief engineer; W. P. Hall, superintendent.

Peace and Prosperity.

Spain has accepted our terms, and it would now appear that the cessation of hostilities is about to take place. Such a condition would in itself bring about a better feeling in business, but all the other conditions are likewise favorable. July has just closed with the largest bank clearings for that month in the history of the country. Crop indications are even better than they were, making the third good harvest in succession, and the iron and steel situation has materially improved. Business failures are at low ebb, being only 189 for the week, as compared with 214 a year ago. Nearly all lines of distributive trade are brisk, and the summer dullness already draws to its close.

In the stock market, there is a distinct upward tendency, and the sales of bonds have been remarkably large. During the

week 26,125 shares of Western Union were sold, rising to 94¼. General Electric was stronger, with sales of 12,450 shares, up to 40¼. New York Edison was firm at 131. In Boston, American Bell Telephone was up around 280.

Copper. New York is steady at 11.50 cents. Heavy steel rail, Eastern mill, is quoted higher at \$17.75.

Classified Digest of U. S. Electrical Patents Issued July 19, 1898.

Batteries, Secondary:—

GALVANIC CELL. A. Heil, Fränkisch Crumbach, Germany, 607,590. Filed Dec. 1, 1897. Comprises a carbon electrode surrounded by about equal parts of graphite, manganese, peroxide, and lead peroxide; a zinc electrode and an absorbent filling holding an electrolyte of zinc sulphate containing flocks of hydrate of zinc evenly distributed throughout the mass of the electrolyte.

Conductors, Conduits and Insulators:—

BOND FOR ELECTRIC CONDUCTORS. S. W. Huff, Baltimore, Md., 607,746. Filed Aug. 29, 1896. Formed of flat metal and comprises a body portion of an integral external extension bent about an axis transverse to the body portion into a tubular attaching-lug projecting laterally from the flat body portion.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. B. G. Lamme, Pittsburgh, Pa., 607,621. Filed Jan. 28, 1897. A three-wire system employing transformers to transform alternating into direct current.

CIRCUIT ARRANGEMENT FOR ELECTRICAL APPARATUS. J. Meisler, Vienna, Austria-Hungary, 607,760. Filed Dec. 13, 1897. Means whereby a number of electrical circuits or separate pieces of apparatus may be simultaneously controlled from different positions through the medium of any one of a number of circuit controlling devices.

Dynamos and Motors:—

ELECTROMAGNETIC MOTOR. A. B. McMillan, New York, 607,451. Filed July 7, 1898. Comprising a motor having an armature and field magnet, and a secondary armature acted upon inductively by a rotating field of force produced by the rotating element of the motor.

DYNAMO ELECTRIC MACHINE. W. B. Sayers, Glasgow, Scotland, 607,593. Filed eDec. 21, 1897. Details of construction.

FIELD MAGNET FOR ELECTRIC MACHINES. S. H. Short, Cleveland, Ohio, 607,609. Filed May 4, 1896. Comprises a series of laminations, whereby the continuity of the end surface of the cores is broken, combined with a ring of magnetic material arranged to surround the armature end of each of the cores.

DYNAMO ELECTRIC MACHINE. A. G. Eigner, St. Petersburg, Russia, 607,737. Filed May 7, 1898. A field magnet for dynamo electric machines, formed of separate complementary members joined together, each of the members having projections cooperating with the projections of another member to form complete polar projections, the members being separated to form slots in the polar projections.

Electro-Chemistry:—

APPARATUS FOR PRODUCING ALKALI METALS FROM THEIR CHLORIDES. P. Danckwardt, New York, 607,506. Filed Jan. 4, 1898. Consists of a double-walled jacket forming a positive compartment, means for passing a current of water through the jacket, and anodes within the compartment, and an iron box open at one side and forming a negative compartment, the box communicating at its open side with the positive compartment.

ELECTROLYTIC BATH. P. Marino, Paris, France, 607,646. Filed Dec. 1, 1896. Consists in adding to a solution of a salt of the metal to be deposited alkali-metal salts of the same acid and an alkali-earth-metal salt of another acid in such quantity as to give by an incomplete double decomposition, an insoluble precipitate and a mixed solution of different soluble salts of the metal to be deposited, and electrolyzing the mixed solution.

Lamps and Apparatuses:—

ELECTRIC ARC LAMP. J. H. J. Haines, New York, 607,598. Filed Oct. 28, 1896. Employs a detached tilting clutch freely movable about its axis and provided on its inner periphery with rotary friction devices.

Measurement:—

VOLTMETER. J. F. Stevens, Philadelphia, 607,715. Filed April 22, 1897. Consists of a resistance coil connected in shunt across the terminals of the working coil, and provided with a core and casing of iron which forms a magnetic circuit, the amount of iron being sufficient not to be saturated by the current passing through the instrument.

Miscellaneous:—

APPARATUS FOR CLEANING PAINT FROM SHIPS. W. P. Freeman, New York, 607,794. Filed June 22, 1897. A reciprocating tool-bar, and electric motor therefor, a tool-bar extending transversely to the shaft of the motor, through the field magnet and the field-magnet coils.

ELECTRIC STOP-MOTION FOR LOOMS. A. Stephens, Guadalajara, Mexico, 607,714. Filed June 28, 1897. Details of construction.

PROCESS OF AND APPARATUS FOR PRODUCING RELIEFS IN METAL. J. Rieder, Munich, Germany, 607,484. Filed Dec. 21, 1897. Employs electrolysis.

ELECTRIC BUOY. E. W. G. C. Hoffman, Charlottenburg, Germany, 607,745. Filed May 28, 1896. Details of construction.

Railways and Appliances:—

ELECTRIC RAILWAY SYSTEM. S. H. Short, Cleveland, Ohio, 607,610. Filed May 24, 1897. Surface contact system. Details of construction.

ELECTRIC RAILWAY SYSTEM. S. H. Short, Cleveland, Ohio, 607,611. Filed July 9, 1897. Waterproof surface contacts.

TROLLEY BASE. H. G. Taylor, Montreal, Canada, 607,612. Filed Sept. 27, 1897. The base is pivotally mounted, the pole is held in an upright position by means of springs, and a buffer is provided to hold the pole when leaving the wire.

ELECTRIC RAILROAD. C. A. Myers, Atlantic City, N. J., 607,697. Filed Nov. 18, 1897. A track rail, comprising two sections, spaced apart and forming opposite walls of a conduit the tread of one section being below the plane of the other section-tread, an insulating material arranged in a groove in the under side of each section-tread, and conductors for electricity, supported by the insulating material.

Regulation:—

REGULATING SWITCH FOR ELECTRIC CIRCUITS. H. P. Davis, Pittsburgh; and G. Wright, Wilkensburg, Pa., 607,617. Filed Sept. 18, 1897. Particularly designed for raising and lowering the electromotive forces in alternating current circuits.

Switches, Cut-Outs Rheostats, Etc.:—

ELECTRICAL RESISTANCE. H. S. Chase, Boston, Mass., 607,540. Filed Jan. 11, 1897. Rheostat of the "enameled" type.

ELECTRIC REGULATOR. J. A. Powers, Lansingburg, N. Y., 607,551. Filed Oct. 28, 1897. A variable resistance, comprising two receptacles containing a conducting solution and communicating at different levels, means for cooling the solution in one receptacle, separable plates in the other, and a solenoid and core for varying the distance between the plates.

RHEOSTAT. M. J. Shiels, Westfield, N. J., 607,608. Filed Jan. 7, 1898. The resistance coils are embedded in cement and the cement enclosed with a metallic casing designed to radiate heat.

ELECTRIC LINE SWITCH. A. B. Du Pont, Detroit, Mich., 607,638. Filed Aug. 12, 1897. Comprises a pivoted tongue, a magnet and spring for controlling the position of the tongue, a ribbed section, connected through the magnet-coil with the main conductor, at each end of the tongue, and roofs protecting the tongue, ribbed sections and magnet.

CONTROLLER. T. Von Zweigbergk, Cleveland, Ohio, 607,672. Filed April 8, 1898. A blow-out for controllers, composed of a series of coils standing in the space between the contacts and adapted to be connected in a circuit and throw their lines of force directly through the contacts.

Telephones:—

LONG DISTANCE TELEPHONE. P. De Kilduchevsky, London, Eng., 607,801. Filed Feb. 10, 1897. Embodies an attached lining of granular non-hygroscopic material in the transmitter.

Classified Digest of U. S. Electrical Patents Issued July 26, 1898.

Alarms and Signals:—

METALLIC GATE-SCREEN. A. P. Prichard, Tacoma, Wash., 607,877. Filed Sept. 9, 1897. A screen for vaults, safes, etc., employed to establish an electric circuit and sound an alarm.

RAILWAY SIGNAL SYSTEM. G. T. Cunningham, Boston, Mass., 608,081. Filed Nov. 13, 1897. Details of construction.

ANNUNCIATOR GAS FIXTURE. J. L. Bixby, Arlington, Mass., 608,100. Filed Nov. 28, 1897. Comprises a cock having a passage connecting its inlet and outlet; a valve controlling that passage; a spring plunger controlling that valve, and a cam to move the plunger and automatically hold it when in its elevated position, against the force of its spring.

Batteries, Secondary:—

SECONDARY BATTERY. G. Walter, Strasburg, Germany, 608,015. Filed Aug. 19, 1897. An instrument for removing detached material from storage batteries, consisting of a box-shaped spatula with a handle, and with ridges extending crosswise of the box, the rear side of the box being closed and the lower end being in the form of a thin flat wall.

Conductors, Conduits and Insulators:—

INTERIOR CONDUIT. E. E. and F. W. Erickson, Boston, Mass., 607,989. Filed June 3, 1898. Comprises an outlet box having its bottom and sides formed from a single piece of thin metal sheet, cut at its corners to provide lapping joints; with a metal brace riveted to each of the lapping joints, having a screw thread in its upper end, and a metal cover having a central opening surrounded by an outwardly projecting flange.

Dynamos and Motors:—

MEANS FOR PREVENTING STRAY MAGNETISM IN DYNAMO ELECTRIC MACHINES. J. F. Kelly, Pittsfield, Mass., 608,133. Filed May 27, 1898. Embodies an energizing coil and a magnetic part within the influence of the coil, in which the coil sets up a magneto-motive force, combined with a coil surrounding the part, and adapted to produce therein a magneto-motive force which neutralizes and prevents the passage through the part of the magnetic flux produced by the first force.

COMMUTATOR BRUSH HOLDER FOR DYNAMO ELECTRIC MACHINES. R. Lundell, New York, 608,135. Filed Feb. 4, 1898. A brush holder having adjacent brushes rigidly clamped against conducting pieces, which permit them to abut against each other, the conducting blocks in turn being securely fastened to an arm by means of flexible springs.

ELECTROMOTOR FOR ELECTRICALLY PROPELLED VEHICLES. A. Siemens, London, Eng., 608,137. Filed Nov. 18, 1897. The pole pieces are arranged partially separate from the limbs of the field magnets and so that they can be readily removed to give access to the armature.

Electro-Therapeutics:—

MAGNETIC ORE SEPARATOR. G. J. Crean, Montreal, Canada, 607,984. Filed Jan. 7, 1898. Comprises a series of stationary magnets arranged in the form of an arc; a hopper located adjacent to the magnets; a rotatable carrier adapted to travel across the surface of and in close proximity to the magnets and intermediate of same and the hopper, and being adapted to receive movement from the ore particles running from the hopper and adhering to it.

Lamps and Apparatuses:—

ELECTRIC LIGHT FOR SURGICAL PURPOSES. W. E. Dow, Braintree, Mass., 608,109. Filed March 28, 1897. Comprises a head-band, a reflector carried thereby, a condensing lens supported in front of the reflector, a lamp mounted between them, and means to adjust the lamp forward or backward relatively to the reflector.

Measurements:—

ELECTRICAL MEASURING INSTRUMENT. G. K. Elphinstone, London, England, and A. C. Heap, Penn, England, 607,921. Filed

May 13, 1898. Comprises an electro-magnetic core, primary windings disposed thereon, a secondary winding, a swinging coil mounted between the poles of the core, and included in closed circuit with secondary winding, and an indicating device operated by the swinging coil.

ELECTROSTATIC MEASURING INSTRUMENT. J. F. Kelly, Pittsfield, Mass., 608,132. Filed April 14, 1898. An electrostatic meter having fixed and movable vanes, a vane electrically connected to a conductor carrying electrical energy, and embedded in a dielectric to prevent creeping of the charge.

Miscellaneous:—

ELECTRIC SOUNDING DEVICE FOR SHIPS. J. P. Buckley, New Orleans, La., 608,104. Filed Dec. 11, 1897. Consists of a sounder adapted to be projected in advance of a ship, an alarm device on the ship, and electric wires connecting the sounder with the alarm device, and a float adjustable on the wires.

BICYCLE LOCK. F. V. Walstrom and J. Erickson, Chicago, Ill., 608,163. Filed May 13, 1897. Comprises a locking mechanism, an alarm separate from the lock, but electrically connected therewith, and a contact device at the lock adapted to be operated by the bicycle upon its insertion.

Railways and Appliances:—

CROSSOVER FOR TROLLEY SYSTEMS. C. E. Davis, Chicago, Ill., 607,913. Filed Nov. 21, 1896. Details of construction.

ELECTRIC TRAMWAY. A. Diatto, Turin, Italy, 607,919. Filed Dec. 1, 1896. Surface contact system.

ELECTRICALLY SELF-PROPELLING VEHICLE. L. Krieger, Paris, France, 607,997. Filed March 11, 1897. Comprises steering wheels pivotally journaled upon opposite ends of a stationary axle, an electric motor connected to each wheel, and means for varying the speed of either motor to steer the vehicle.

INSULATED RAIL JOINT. G. A. Weber, New York, 608,088. Filed Nov. 5, 1897. Details of construction.

Switches, Cut-Outs, Etc.:—

DEVICE FOR OPERATING ELECTRIC SWITCHES. J. H. Cary, Springfield, Mass., 607,830. Filed Jan. 8, 1898. Especially applicable to telephone systems where it is desired to provide an individual call for separate stations upon the same line.

REVERSING RHEOSTAT. I. E. Storey, Philadelphia, Pa., 608,013. Filed January 29, 1898. Comprises a rotary shaft carrying a crank disc, an abutment on the disc, a toggle lever bearing at one extremity against the abutment and pivoted at a fixed point at the other and a spring connected to the toggle joint.

ELECTRIC CIRCUIT CONTROLLER. R. Lundell, New York, 608,134. Filed Feb. 1, 1898. A circuit breaker consisting of electro-magnetic means for interrupting an electric circuit, in combination with means controlled by the movable part of the circuit breaker, and adapted to force a blast of air around the circuit breaking contacts.

Telephones:—

MICROPHONE. T. J. Howell, London, Eng., 607,994. Filed Jan. 8, 1898. Consists of a honeycomb disc having a series of cells, diaphragm, a screw down cover to hold the diaphragm in place in front of the honeycomb disc, a rear plate extending across the series of cells in the disc and a conducting spring for forcing the rear plate with the honeycomb disc forward as a whole, the cells being filled with carbon granules.

ELECTRIC TELEPHONE SYSTEM FOR HOUSES. L. Plant, New York, 608,076. Filed Sept. 9, 1897. A simplified house telephone for private and apartment houses, by which the speaking tubes and call bells may be dispensed with.

Western Electrical Supply Co.

THE general catalogue of the Western Electrical Supply Co., of St. Louis, Mo., which has just issued from the press and is being distributed among the trade, certainly comes up to the expectation of every one who has seen the advertisement of the same in the various electrical periodicals. It is one of the most complete electrical supply catalogues ever issued, and the company deserve great credit for issuing a book of so much value and so exhaustive in every detail. The catalogue, which contains 753 pages, measures 7x10½ inches, and is handsomely bound in a green cloth cover, plainly but artistically ornamented. It has been the intention of this company to compile a catalogue of standard goods, and while it is well known that they are in a position to furnish everything electrical that the market affords, still their experience has induced them to believe that the assortment shown in this catalogue covers quite completely the lines best suited to the needs of their numerous customers. Special attention is called to the fact that while they carry in stock the products of many of the leading manufacturers, they are agents for several prominent makers of electrical merchandise, such as the Stanley Electric Manufacturing Co., Eddy Electric Manufacturing Co., John A. Roebbling's Sons' Co., India Rubber and Gutta Percha Ins. Co., the Ohio Brass Co., Adams-Bagnall Electric Co., North British Wire Manufacturing Co., and others.

The first portion of the catalogue is devoted to a description of electrical apparatus and machinery for lighting and power purposes. Numerous beautiful half-tone illustrations of various

types of direct and alternating current machines are shown. There are interesting chapters on the coupling of generators, switchboards, alternating current motors and transformers and a lengthy chapter on the application of electric motors for household and factory purposes. Fan motors are described next in order, and a great variety of them are listed. Following this are a number of pages devoted to arc lamps of every description, and full page illustrations accompany the text. Incandescent lighting is the title of the next chapter of this beautiful book, and electric light supplies and switchboard apparatus, as well as switchboards themselves, are included therein. Dynamo brushes, carbon holders and other apparatus are next described, and then follows a chapter on rubber goods, insulating fibres and compounds. Fuse wires and other insulating specialties form the next chapter. Then follow in order sections on the following subjects, each one being a complete catalogue on the subject of which it treats: Electrical heating supplies, testing instruments, construction material, tools and appliances, electric railway supplies, telegraph supplies, telephone and accessories, electric house goods, electric and combination fixtures and leather belting. The last few pages of the book are devoted to an index to trade numbers and one to code words, a very exhaustive index of all appliances shown in the catalogue. A confidential trade discount sheet, numbering 24 pages, accompanies the catalogue when sent to the trade.

As may be imagined, there has been a steady demand for this exhaustive treatise, and while a large edition was published by the company, it is likely to be exhausted within a short time, and any one who wishes to place this valuable book on his shelf had better write for it at once, so that he may not meet with disappointment. We congratulate the company on the enterprise, and trust that this work will prove of as great benefit to them as it certainly must to their customers and the trade in general.

Chambersburg Engineering Co.

Catalogue No. 23, entitled "Hydraulic Machinery," has just been issued by the above company, of Chambersburg, Pa., having an office at 39 Cortlandt street, New York, and one in the Park Building, Pittsburg, Pa. This catalogue contains illustrations and descriptions of a number of hydraulic machines of the company's most recent designs, such as hydraulic riveters, cranes, accumulators, etc. The company also manufacture steam hammers of any desired size, pneumatic machines and steam engines, all of which are described in separate catalogues, which will be sent to any one on application.

Patterson, Gottfried & Hunter.

A special catalogue treating of tapping machines has just been issued by the above company, of 146-150 Centre street, New York, and adds one more to the very useful and instructive machine tool catalogues issued by them. It contains descriptions and illustrations of tapping machines of various sizes and styles manufactured by the numerous companies which this firm represents, and must prove of value to any one owning machine shops or installing machinery of this kind.

Metropolitan Injectors.

The Hayden & Derby Manufacturing Co., 111 Liberty street, New York, are sending out their very beautiful 1898 catalogue, which is a splendid reference book on the subject above mentioned. Several new features have been introduced, giving the horse power not only on the basis of 7½ gallons of water per horse power per hour, which has always been the standard basis of figuring the horse power of injectors, but also giving the horse power on a basis of thirty pounds variation of water per horse power per hour. The catalogue also shows for the first time injectors with flange, as well as screw connections, and all the various forms of injectors which the company manufacture are shown in dimension diagrams, which enables one to lay out a piping from the data given. The catalogue further describes new forms of ejectors, hot water heaters and special injector fittings. The catalogue will be sent to any one on application.

The Bergmann-Elektromotoren and Dynamo Werke Aktiengesellschaft, of Berlin, inform us that they have removed their offices to their newly-erected factory, No. 23 to 24 Oudenarderstrasse, near the Seestrasse, Berlin N. The company maintains only its show rooms at its former address, Berlin C, Spandauerstrasse, 16.

TRADE NOTES AND NOVELTIES

Gold's Improved Electric Car Heating Apparatus.

PROMINENT by its merits and success, the electric heating apparatus of the Gold Street Car Heating Company, of New York and Chicago, is still being developed and perfected, and its advance is a matter of general interest to the community, the heating art being a matter of novelty and one in which very few manufacturing concerns have had any experience worth considering. The heaters manufactured by this company are covered by patents and, we believe, have never been the subject of any litigation or legal controversy. As they embody several new and important features, a description of them preceded by a brief reference to the principles underlying

FIG. 1.—RESISTANCE COIL AND SUPPORT USED IN GOLD'S IMPROVED ELECTRIC HEATER.

their construction will be of interest. The efficiency of an electric heater depends very largely upon the access which the flow of air has over the heated wires. The principle of a free circulation of air through the heater, so that all of the electrical energy developed into heat is utilized to the best advantage by being carried off of the resistance wire and into the car body in an even and steady flow of warmed air has been demonstrated to be the most satisfactory and proven itself the means of warming the cars at the least expense of current.

The object, therefore, has always been to so arrange the construction of these electric heaters that the freest possible circu-

FIG. 2.—FRONT VIEW OF GOLD'S IMPROVED THREE-DEGREE PANEL ELECTRIC HEATER.

lation of air may be had, so that the air as it passes through the heater should be divided into the smallest particles, and each particle of air come in contact with the heated surface, and as a result, carry with it into the car body its full and equal share of the heat generated. It is now and always has been the constant aim of the company to get the benefit in the form of thoroughly warmed air in the car body of all of the electrical current expended in the heater, and the only known practical way of accomplishing this is by having a free circulation of air through the resistance coils.

The construction of the improved Gold heater provides for the features desired. The resistance coils are supported in such

FIG. 3.—INTERIOR VIEW OF GOLD'S IMPROVED THREE-DEGREE PANEL ELECTRIC HEATER.

a way that the support itself, while holding the wire firmly in place and not permitting vibration, will offer the smallest possible amount of friction to the flow of air through the heater. This new method is shown in Fig. 1, and as can be readily seen from the illustration, this method of supporting the resistance coil of an electric heater is quite novel and is radically different from anything of a like character that has ever been attempted. It is compact, efficient, simple and durable.

This support consists of a one-quarter inch steel rod, which is thoroughly covered with an insulating enamel and which enamel is burned on the rod at over two thousand degrees of heat. It is, therefore, not affected by any heat to which it will ever be subjected, and is at the same time an absolute non-conductor. This rod is shaped in a zig-zag form, and the resistance with absolute non-corrosive qualities. This wire is shown by the illustration in Fig. 1. Special attention has been

FIG. 4.—PLAN OF CAR EQUIPPED WITH GOLD HEATER SHOWN IN FIGS. 2 AND 3.

given to the composition of the resistance wire used in these coils, and in that which is now produced is combined a high resistance with absolute non-corrosive qualities. This wire is the company's own product and it is the result of long and careful experimenting.

It has been tried under all sorts of conditions and has never been known to fail. The result shown by this wire has made a very great demand for it, as it has earned the complete approval of every one who has used it.

The resistance coil is wound on an open pitch, so that when it is placed on the zig-zag rod the wire is in its natural condi-

FIG. 5.—GOLD STANDARD ELECTRIC HEATER.

tion and is not subjected to any strain whatever. It has only tension enough to keep it firmly in place. The many advantages of this method of construction are apparent. A large amount of wire is secured in a small space without resorting to the use of a bulky and solid core. This construction is certainly the acme of simplicity. There is no bulky core to obstruct the passage of the air, but, on the contrary, the very freest circulation of air through the coil takes place, and it is a known fact that to thoroughly heat air it must be circulated, or, in other words, must be divided up into the smallest particles and passed over the heated surfaces.

The wire is evenly heated over the entire surface and always maintains its original and natural condition. In the improbable event of a wire breaking it would be held fast on the supporting rod, whereas, in heaters which have the wire wound around on

FIG. 6.—PLAN OF CROSS-SEAT CAR EQUIPPED WITH 12 GOLD ELECTRIC HEATERS.

a core under tension, when a wire does break it will unwind and short-circuit with the heater casing.

This improved construction is used in all of the electric heaters which are now being manufactured, and the results given by it in the many different forms of heaters are all that could be desired.

Fig. 2 shows the most improved form of electric car heater. This heater has the coils so arranged that the upper sets are heater being flush with the panel. It is the standard size of such electric heaters in use to-day. Like all of the apparatus, it is solidly built, the mechanical details are all perfect and it is very easily applied. Fig. 3 shows the interior. It is lined with asbestos and has an air space provided at the top as shown. This heater has the coils so arranged that the upper sets are in multiple and the lower set in single series. It is usual to apply six of these heaters to a car of about twenty-four foot body and graduate the heat into three different degrees by turning the handle of the switch to any of the three points noted on the dial.

A specially constructed switch is used with which the first or lowest degree, the second or medium degree, or the third and hottest degree may be had by turning the handle of the

switch to points 1, 2 or 3, noted on the dial, for such degree of heat as may be desired.

Fig. 4 shows a plan of a car equipped with six Gold heaters, having the three degrees on each heater. When the regulating switch is turned to the first point the current passes through the lower set of coils of every heater; at point number two the lower set of coils is cut out and the current passes through the upper sets in every heater in parallel series, and at point number three the current passes in multiple series through all the coils of every heater in the car, and, as a consequence, all of the heaters distribute the warmed air at an even temperature at all times, no matter at which point the switch may be set, thus maintaining in the simplest possible manner a perfect regulation of temperature which is even, agreeable and uniform in all parts of the car.

The regulating switches, as well as all other parts used in these electric heating equipments are as simple as it is possible to make them, and their durability is guaranteed. All of the material used for the appliances is of the best quality to be obtained in the market, the workmanship is first class in every respect and a great deal of mechanical skill and ability is embodied in the heaters which are now being produced. The company carry in stock a great many different styles and designs of electric heaters.

With reference to the principle of complete circulation of air through the resistance coil, it can be plainly seen that heaters having the resistance wires imbedded in asbestos or other such material cannot be as efficient or as durable as a heater in which this improved construction is used.

Fig. 5 shows a view of the Gold Standard Electric Heater. This heater consists of three Gold improved resistance coils and supports shown in Fig. 1, in series. These rest in porcelain plugs or caps at either end and are encased in a cylindrical perforated sheet-iron casing, as shown. This heater is 3 inches in diameter and about 20 inches long. It has been greatly admired for its simple construction and surprising efficiency. It is particularly adapted for cross-seat cars, elevated railway or regular railroad cars which are propelled by electricity.

Fig. 6 shows a plan of cross-seat street car equipped with twelve Gold standard electric heaters, controlled by a two-point regulating switch.

A great advantage of this Gold standard heater is that, being of such compact form, it is a very desirable size and style with railroads, as it can be used in so many different positions.

Perfect uniformity of distribution of the heat can always be secured from this style of heater, for they can be placed about the car in such a way that this condition can always be maintained. They are very light in weight and their durability is guaranteed. These Gold standard heaters can be wired for two graduations on each heater.

Besides manufacturing the car heaters described above, the company have constructed a number of electric heaters of different styles and sizes for dwellings, office buildings, etc. Portable heaters of high efficiency and neat design is also one of their specialty and have won universal favor.

Cleveland Electric Co., Cleveland, Ohio.

THIS company, well known in the electrical field as manufacturers of electrical appliances have directed their chief energies to the manufacture of two specialties, one known as an automatic time switch (Fig. 1), the other a high tension arc cut-outs (Figs. 2 and 3). The former are made in various sizes up to 200 ampere capacity and are designed for use in automatically closing or opening electric light or power circuits. The device as shown in Fig. 1 consists of an eight-day clock movement, but without hands, placed in the middle of a metal case, a two or three pole, double brake knife-blade switch placed below the clock, with an electromagnet in a circular case, above which actuates a lever that passes behind the clock and connects with the movable parts of the switch. The action of the switch is adjusted by means of two discs or dials, one being larger than the other, and both mounted on the hour stem of the clock movement, being held in position by means of a thumb screw. Each of the discs is divided into sections representing the hours of a day, and each has a notch in its periphery, at the zero point, into which a contact arm drops when the time for switching arrives, that on the small disc closing the circuit and the one on the large disc opening

it, so that by properly adjusting the discs, the switch will act at any pre-determined time. The current that energizes the magnet is cut out as soon as the switch acts so that the flow of the current through the magnet coils is only for a moment, and thus avoids any injury to the magnets from any excessive

FIG. 1.—FRONT VIEW OF CLEVELAND AUTOMATIC ELECTRIC TIME SWITCH, IN CASE.

flow of current. The armature, which operates the switch lever, is thrown back and forth by means of two coils, which are placed in either end of the circular case, the armature terminating at each end in a large washer and the direction of the movement depends upon which of these coils receives the current. The disc being set, the action of the switch will occur at the same hour every day with no further attention, except to wind the clock once a week. The switch does not interfere, however, with the regular cutting in or out switch, which may be operated at any time as before. It will be seen that the use of the switch will work a saving to any consumer who uses current on a meter basis, and it is likewise of advantage to the

FIG. 2.—CLEVELAND ARC CUT-OUT, WITH COVER ON.

producer, as it saves time consumed in switching, besides there is a gain in having light switched on or off at the same time. The clock mechanism is of German manufacture, and the whole is enclosed in a neat metal case having a door and lock.

The arc cut-out provides for readily cutting in or out one or more lights on high tension arc circuits. The switching mechanism is enclosed in a circular-iron case, with a close fit-

ting waterproof cover, which is about ten inches in diameter. The levers are mounted on a porcelain base within the case with porcelain thimbles in the side of the case for receiving the line connections. The handle is of hard wood and the connecting bar between the handle and contact arms is made from fibre insulation. A flat spring, curved to conform to the exterior of the case, serves to throw the switch quickly, as the handle passes the centre, preventing a protracted arc.

The works are located on the fifth floor of the Marine Building, 14 Middle street, Cleveland. The tool equipment consists of iron working and stamping machines of such number and de-

FIG. 3.—CLEVELAND ARC CUT-OUT, COVER REMOVED.

sign as to meet all the requirements for building the various parts with the exception of the clock mechanism which, as before stated, is of German manufacture. Auxiliary to the tool equipment is a generator which supplies current for lighting the shops and also for testing the appliances, it being the practice to submit each device to a thorough current test before shipping.

The affairs of the company are under the management of Mr. Frank Rogers, who is also superintendent of the works. Mr. Rogers has long been at work in the electrical field, having been in the employ of the Brush Electric Co. for many years.

Westinghouse Dynamos and Engines for Europe.

THE Westinghouse Machine Co. and the Westinghouse Electric and Manufacturing Co., on the afternoon of Saturday, July 30, invited a large number of prominent engineers to their works at East Pittsburg, primarily to inspect some five new engines and electric apparatus which are about to be shipped to England. The visitors saw three 2,500-horse-power electrical generators, direct connected to three 2,500-horse-power engines, which were constructed for the Metropolitan Electric Supply Co., of London. Their present contract with the Westinghouse interests calls for three compound two-phase steam alternators, each consisting of an enclosed vertical compound engine with the armature of the generator coupled direct to the engine crank shaft, the engine and generator being mounted on separate bed plates.

The engines and generators are so designed that the full output can be obtained at any speed from 116 to 145 revolutions per minute, this range of speed being necessary in order to provide a variation in the frequency of the alternations, and thus enabling a supply to be given to existing transformers in London.

The engines are of the enclosed vertical compound marine type, long since popularized by the Westinghouse companies, and they are the most powerful engines yet made at East Pittsburg.

The electrical apparatus built by the Westinghouse Electric and Manufacturing Co., accompanying these engines, consists of

three direct connected alternating current generators, each having a nominal output of 2,000 horse power and delivering two-phase currents at a pressure of 500 volts. The armature, or the revolving element, of each generator, as before mentioned, is mounted directly on the engine shaft.

There is one direct current multipolar exciter to each generator, which is arranged for direct connection to the engine shaft.

This plant is to supply primarily arc and incandescent lighting to London, but a portion of the power is to be used for operating rotary transformers, which in turn supply current to direct current motors, and for charging storage batteries by the three-wire D. C. system.

Apart from the machines contracted for by the Metropolitan Electric Supply Company, the gas engines and the steam turbines at the Westinghouse Machine Co.'s works are particularly noteworthy. The Gas Engine Department is doing a large business, turning out engines from 10 to 200 brake horse power and shipping them all over the country. The principle on which they run is a modification of the well-known Beau de Rochas cycle. This consists of compressing the charge into the head of the cylinder before igniting it. These engines differ from the ordinary type in that the governor acts by controlling the quantity of explosive mixture which is taken into the cylinder. This results in an adjustment of the power of each explosion to the amount of work being done; hence the engine runs with the steadiness and regularity of a first-class steam engine. The regulation is so perfect that the company has built many direct connected rigs where the dynamo is mounted rigidly on the end of the engine shaft. Even under this most severe test the lights are perfectly steady.

The Westinghouse Machine Co. have also been reaching forward and have successfully built a 650 brake horse power gas engine. This engine has three cylinders, each 25 inches in diameter, and a 30-inch stroke, and runs at 145 revolutions per minute. Its economy is very marked, resulting in the production of a brake horse power for 11 cubic feet of natural gas. This is the largest gas engine in the world, and it operates with complete success.

A Parsons' steam turbine driving a 200 horse-power alternating current generator was particularly interesting to the visitors.

The turbine on exhibition runs at 4,700 revolutions per minute without any perceptible vibration. This speed, however, is not limited in any way. It may be either higher or lower. The bearings, which are a special feature, admit of any rotative speed that might be desired.

The Cabinet Mfg. Co. of Steubenville, O.

CABINETS and cases for housing electrical appliances, constitute the principal output of the works of this company, and, of these, telephone cases of every description predominate. The product, however, is not confined entirely to this class of goods, but embraces, according to the demand, fancy cases of every description, such as jewelry boxes, cases for travelers' toilet sets and medicine cases. The company enjoys exceptional facilities for filling all orders, for high grade goods, and among these facilities may be noted, the locality. The region produces, in abundance, a fine quality of oak and black walnut timber, which is the chief material employed, and which is purchased first hand from the farmers, who deliver it with their own teams directly to the storage yards of the company. Again, the employés are of a higher order of intelligence and possessed of a degree of mechanical skill above the usual run of mechanics; and third, the factory equipment embraces the latest up-to-date wood working and finishing machines that are to be had. The factory building, which is a four-story brick structure, is located near the business centre of the city and extends across the block from Fourth to Fifth streets. The lumber yard adjoins, and the course of the material is first to the re-sawing department, which is located in the basement and where by band and cross cut saws it is cut into proper thickness and length for the drying kilns. Power for operating the saws is furnished by a 100 h. p. engine, while there are two other engines driving other machinery and the fans at the drying kilns. Steam is generated in a 130 h. p. battery of tubular boilers, the fuel consisting of shavings and coal, the former being delivered to the fire room by means of a system of exhaust pipes, which take up all the shavings

and dust from each machine and deliver it through a separating head into the fire room. The shafting for driving the tools of each department is located under the floors and is so provided with clutches that the machines of any department may be started or cut out independent of those on the other floor.

The drying kilns, of which there are five, and which have a capacity each for 14,000 or 15,000 feet of lumber, occupy a separate building 100 x 18 feet and are constructed on what is known as the "common sense" plan. Each room is provided with a nest of one-inch steam pipes, which are placed beneath the floor and there are flues in the ceiling, through which the moist air is drawn by means of a fan, when it is directed into a case containing a coil of cold water pipes upon which the moisture condenses, and from which the dry air is again returned to the kiln. In the process of seasoning, the room is first filled with live steam under pressure, which is designed to drive the sap out of the pores of the wood. This is followed by the heat which is increased by stages until quite a high temperature is reached, exhaust steam being employed during the day and live steam from the boilers at night. The period for seasoning is about fifteen days, so that the kilns are each replenished twice a month. The material is now taken to the second floor of the main building by an elevator and is here

TELEPHONE CABINETS MANUFACTURED BY THE CABINET MFG. CO., STEUBENVILLE, OHIO.

planed and sawn into varying dimensions suitable to each part of the case, and the different parts are numbered so that they accompany each other in groups through all the departments to the assembling rooms. On the next floor the material is introduced to the machines known as jointers, tickers and moulders, and here the fitting is continued; one of the most interesting machines being a "locked corner cutter," on which miniature tenons and mortises are cut in the ends of such pieces as are designed for box sides, so that most of the work is put together by mechanical fits and held in place by glue without the use of brads or screws. There are numerous sandpapering machines on which the parts are carefully smoothed up, except such mouldings as require hand work. Here is also a round cornering machine by means of which the corners are rounded off after parts have been glued together.

The assembling and gluing department occupy part of the third floor and here the process of shaping begins and numerous clamps and racks are provided for holding the parts together till the glue has set. In this department is an ingenious squaring machine or press having adjustable arms which, on being closed by a hand lever, bring all the box shapes to perfectly square angles without the process of measuring and hand adjustment. The half finished parts pass back and forth between the gluing and fitting departments till all the odd shaped pieces are added, when the cases are advanced to the varnishing and finishing department which occupies the top floor, and for which work female help is chiefly employed. Here coat after coat of filling material is applied and rubbed down with oil and pulverized pumice stone, when the coats of varnish follow with repeated rubbing until the grain is thoroughly brought out and the surface shines like a mirror. Cases are now ready for final inspection and go to the shipping depart-

ment, where they are carefully wrapped in paper and crated for shipment. The company not only manufacture cases from their own designs, but give special attention to exclusive designs furnished by customers. The executive offices occupy the first floor on the street side of the building, and the affairs of the company are under the management of Mr. M. T. James.

The National Electric Co.

THE name, electric, generally conveys the idea of a manufacturer of electric machinery or appliances, for the generating or control of electric energy, but in this case it represents an industry that is closely allied to manufacture, except it is mending instead of making and is one to which all users of electric machines must sooner or later resort. It is well understood that the reconstruction and repairing of electric machinery requires as much care for perfect workmanship and durability and involves as much genius usually as is displayed in designing and constructing original machines. As the work furnishes practical experience, it goes without saying that one engaged for eighteen years, as in the case of the manager of this company, in the building and repair of electric machinery, will be able to do the work right and with a stronger guarantee of success than can be furnished by mechanics inexperienced in this line of work. This fact the users of electricity are coming to see, and many companies that were formerly doing their own repairs are finding that it is profitable to have it done by professionals, even with the freight charges added, so that this company enjoys a patronage from nearly all parts of the country.

"General electrical repairs" is the term used to designate the work, and the line includes rewinding and repairing armatures of every type and size, especially the armatures from large machines. It also includes the making and repairing of commutators, transformers, and the making of duplicate parts, including the armatures of any electrical machine. The works occupy a three-story brick building, 15 Michigan street, and the equipment of tools is very complete. The large tools occupy the ground floor, while the smaller tools and the store room are located on the upper floors. The tools are all operated by electric power from current obtained from the city lighting plant. Among the special appliances may be noted the process for balancing armatures after they have been rewound. This consists of a stone foundation, independent of the building floor and foundation, on which are placed sets of metal ways according to the size of the armature to be balanced and so arranged with adjusting mechanism that an absolute level may be secured, making a very important point in securing a perfect balance. On the same floor is a baking box, or oven, so arranged with end doors that the largest armature may be placed in position by means of a truck without any lifting. The company makes a specialty of rebuilding defective generators, or such as need to be redesigned to suit the demands of new lamp conditions, especially where the enclosed arc is replacing the open arc type of lamps, as where the latter require about 9½ amperes, the enclosed type requires only 6½ amperes. For this reason a change in the windings of generators becomes a necessity. The works are not wholly confined to repairs, but small motors for any purpose are built and motors and experimental machines are built for inventors and engineers. Second-hand machines are also bought and sold.

The management of the company is in the hands of Mr. J. E. Elliott, who, as said above, has had eighteen years' experience in electrical work, having begun with electrical training in the shops of the Brush Company in 1880. For this reason and also because the employees are all skilled in their various lines, the company are able to guarantee the work and assure their patrons that where durability is taken into consideration they can effect a decided saving over home-made repairs.

Ball Engine Sales.

The village of Richmond, Mich., is to have a new electric light plant. The new electrical apparatus is to be furnished by the Westinghouse Electric and Manufacturing Co., and the steam plant by the Ball Engine Co., Erie, Pa.

One of the most complete isolated electric plants in Columbus, O., will be that of the Peruna Drug Mfg. Co., now being installed. Ball engines aggregating 550 horse power, direct connected to Siemens-Halske generators, furnish the power.

The W. E. Petite Enclosed Long Burning Arc Lamp.

The Western Electric Company, in placing upon the market its new long-burning arc lamp used the name "Midget" in describing it, owing to its size, the lamp being but 20 inches in length. The name "Midget," however, is no longer used by them in describing this lamp, but the name "W. E. Petite" has been adopted.

NEW YORK NOTES.

THE GUGGENHEIM SMELTING CO. are making extensive additions to their refining plant at Perth Amboy, N. J. The buildings they are putting up will be fireproof throughout, being constructed of steel framework covered with corrugated iron. The contract for furnishing and erecting these buildings has been let to the Berlin Iron Bridge Company, of East Berlin, Conn. The Berlin Iron Bridge Company have lately shipped to Mexico two large buildings for the same company.

CHANGEABLE ILLUMINATING INDICATOR CO., of New York City, has been formed. Capital, \$40,000, and directors: William E. Finn, David L. Phillips, Lewis J. Phillips, Geo. W. Tallman, Harturg J. Phillips.

NEW ENGLAND NOTES.

G. M. ANGIER & CO., 64 Federal street, Boston, Mass., have done a shrewd thing by issuing a neat card which gives the "War Taxes," so that at a glance one can see what stamp or tax is required for any document or transaction within the provisions of the new law. The card is so printed that it can be hung up in an office.

ADVERTISERS' HINTS.

F. S. BLACKALL, of the firm of Blackall & Baldwin, 39 Cortlandt street, New York, is at present advertising for bids for the extension of the Shanghai, China, municipal plant. Mr. Blackall offers to forward to the council literature from manufacturers of electrical apparatus, tools and supplies, if they will send same in duplicate to him.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, always have a full supply of glass insulators for telegraph, telephone and electric light work.

G. C. WOOLVERTON, 442-446 Niagara street, Buffalo, N. Y., has succeeded the Woolverton-Elliott Electric Co., and will continue the extensive repair business the late concern built up.

THE EDDY ELECTRIC MFG. CO., Windsor, Conn., illustrate one of their large direct-connected units. This type of generator is very fully described.

SEATON M. SCOTT, 123 Liberty street, New York, makes a specialty of the design and supervision of central stations.

WESTINGHOUSE ELECTRIC & MFG. CO. have recently been called upon to furnish three 2,500 h. p. generators to the Metropolitan Electric Supply Co., of London, Eng.

H. W. JOHNS MFG. CO. call attention to the fact that Vulcabeston products being heat-proof are particularly adapted to use in arc lamps and make a specialty of parts for that purpose.

THE COLUMBIA INCANDESCENT LAMP CO., who have adopted for their trade-mark "Unequalled in Quality," invite central station managers and others to make a most rigid test of their product with respect to those points which go to make a successful incandescent lamp.

THE AMERICAN ENGINE CO. call attention to their generators and motors, both belted and direct connected, for all purposes.

J. JONES & SON at the very outset of the fall season advertise a desk clamp which will fit any roll top desk, thus keeping

an incandescent lamp in a handy position where it will radiate the most light.

THE WALKER CO. show in their advertisement an illustration of the field and armature of their alternating current generators, which are built in different phases at 40 or 60 cycles, and announce that at the present time they have in process of construction over 25,000 h. p. of this type of machinery.

GORDON BATTERY CO. is now the name of the company marketing the Gordon Primary Cell, which has many points of excellence.

ELECTRIC STORAGE BATTERY CO. present a testimonial letter from a battery user, who has found in an experience of over one year with one installation that the Chloride Accumulator is an economy in a well-regulated plant.

POWER GENERATORS are treated of in the announcement of the C & C Electric Co. for railway work as well as stationary service.

THE NEXT NEW YORK TELEPHONE DIRECTORY goes to press September 1. Intending subscribers have a little more than two weeks in which to be represented in it.

The Electrical Engineer.

Vol. XXVI.

AUGUST 18, 1898.

No. 537.

The Central District and Printing Telegraph Co.— Bell Telephone Interests in Pittsburg.

BY C. B. FAIRCHILD.

THIS is an odd name for a telephone company, but it is explained by the fact that when originally incorporated, it was designed to operate the Gray automatic printing telegraph instrument, as a branch of the Western Union business. It is now a telephone company, but supplies current for operating messenger call boxes for the Western Union Telegraph Co. of

FIG. 1.—TERMINAL ROOM OF PITTSBURG TELEPHONE EXCHANGE.

this city. The territory covered by the company's franchise includes Western Pennsylvania, Eastern Ohio and West Virginia. The number of subscribers in May of this year, in the whole territory, was 19,397, of whom 7,095 are in the Pittsburg district, there being 2,923 in the Pittsburg main exchange, from which they operate 159 branches and over 700 public pay stations. Some idea of the magnitude of the business may be had from the statement that on May 10, the number of calls in the Pittsburg district was 97,042. The company occupies its own seven-story building on Seventh avenue, which was specially designed for the telephone business. The terminal room is located in the basement, illustrated in Fig. 1, and here the wires for the 4,200 lines are brought out from the cables in pairs of twenty. About 68 per cent. of the lines are metallic circuit. The main power station of the building is also located in the basement, and the equipment consists of two 50 h. p. Ball engines and two 400-lamp generators. Adjoining the engine room are a motor and seven small generators for supplying current to operate the messenger boxes, private telegraph lines and subscribers' desk telephones. A portion of the first floor and an adjoining building are used for the storage of material and for the setting up of telephones. The trouble department also occupies a room on this floor. In connection with the testing apparatus, is a small motor which supplies the current for operating the testing instruments. A fireproof cable tower extends from the basement to the top floor. This is said to be one of the best designed and most convenient cable towers to be found in any city. In this is placed a series of iron ladders, for convenience of placing the cables, and which can be used as a fire escape, should it become necessary. The telephone power room proper, illustrated in Fig. 2, is located on the top floor, and has an auxiliary storage battery equipment of six cells. There is a small generator with which the batteries are charged at night. These supply the current for the transmitters. Two other generators supply the current for the first class exchanges and other purposes.

The operating department occupies the seventh floor, which is a large, airy room, and the main switchboard extends along

two sides, with an auxiliary board on the opposite side, and the manager's desk is near the middle of the room. The board accommodates sixty-two operators, and it is divided according to the requirements of the service for regular subscribers, trunk lines, pay stations, automatic local tolls and the long distance trunk lines. Some of the special features of the board include two miniature pilot lights on each panel, one white, the other red, to indicate the call, and when rung off. Some of the shutters are marked and striped in various colors, to indicate the character of the service being rendered the subscriber connected. The outgoing call panels of the toll board are provided with calculagraphs, which are placed flush with the counter, exposing the face of the clock. The record cards are inserted in a slot under the face when a call is made. The operator pulls a lever on the right and the time connection is made as indicated on a card by a printed dial. When the number is rung off, the operator pushes a lever at the left, and another dial is printed, indicating the time the communication ends. These cards also contain the number of the telephone calling and the operator's number. The average number of calls answered per hour per operator is usually about one hundred and forty, the maximum, two hundred, but when the latter number is reached the lines are re-distributed on the board. Ten trunk lines connect with the office of the long distance system on the outskirts of the city, seven miles from the central exchange. The charge for unlimited service per year is \$125. A measured service is also provided, as per the subjoined schedule: Long distance residence telephones, 400 "out" calls per annum. No limit to "in" calls. Four party lines, \$30, additional calls 5 cents each, or \$4 per annum. Schedule of special and party lines measured service for business and residence use:

No. of calls.	1 party.	2 parties.	3 parties.	4 parties.	Extra calls.
600	\$60	\$50	\$42	\$39	7c.
700	66	56	48	45	6c.
800	71	61	53	50	5c.
900	75	65	57	54	5c.
1,000	78	68	60	57	5c.
1,100	81	71	63	60	5c.
1,200	84	74	66	63	5c.

In breaking in new operators, they spend two or three days watching one of the regular operators, and listening to the calls in answer, and when accepted, they are put on the half-day

FIG. 2.—POWER ROOM OF PITTSBURG TELEPHONE EXCHANGE.

work, which begins at five and ends at ten o'clock p. m., for which they receive \$15 per month. The next shift from ten to seven o'clock a. m. receive \$25 per month. The regular day operators work ten hours, with forty-five minutes for lunch, and receive from \$25 to \$35 per month, depending upon the length of service, the maximum being reached after four years in the company's employ. The monitors and assistant chief operators receive \$50 per month. The manager, Mr. S. M. Morrell, does not regard the work as being especially hard on the operators, some of whom have been at the business for fifteen years in this exchange. The list of applicants is usually 150 ahead.

The company operate about 300 sub toll stations in connection with the Pittsburg Exchange system. These stations are located at convenient points throughout the district and are extensively used by parties whose business or social requirements do not justify subscription for regular exchange service.

The toll slot machines of the Gray telephone pay station type are used for many of these stations, and the service rendered is generally very satisfactory.

The business offices of the company are conveniently located on the different floors of the building, and the number of employees and canvassers is about 275. Mr. D. Leet Wilson, president Fort Pitt National Bank, is president; Mr. D. F. Henry, formerly well known in the street railway field, is vice-president; Mr. D. Paynter is superintendent; Mr. J. G. Stoakes, secretary and auditor, and J. M. Stephenson, treasurer.

Motor Generators for the Chicago Fire Alarm System.

SOME time ago the Chicago city fire alarm under the supervision of the new city electrician, E. B. Ellicott, and assistant city electrician in immediate charge of the fire alarm system, D. M. Hyland, was improved by the substitution of storage batteries for the gravity batteries which for years had been employed for the fire alarm circuits. In connection with this change, other apparatus has been put in which is of interest.

The fire alarm system of Chicago, as in all the large cities of this country, is a closed circuit system; that is, a small amount of current is kept flowing constantly through the circuit, the alarm boxes are placed in series on the circuit, and the fire alarm signals are made by the momentary opening of the circuit by a signal street box. Absolute reliability and constancy are of course essential features of any current supply for this class of work. The storage batteries recently purchased by the department offered the feature of reliability and constitute a reserve that can be depended on as long as the building containing them stands. It is necessary, however, to provide for supplying the fire alarm circuits when the batteries are being charged, and to do this the outfit here described and illustrated has been put in. It consists of a set of motor generators adapted to be run from a 110 volt circuit. Each motor generator consists of a 110 volt motor, for direct current, directly connected through a flexible coupling to a direct current dynamo of a voltage suited to the particular fire alarm circuit it is desired to supply. The two machines are set on the same bed plate. Fig. 1 shows the connections of a motor generator and fire alarm circuit, while Fig. 2 shows the set of motor generators installed for the Chicago fire alarm system. The motor is shunt wound, as is also the generator, so that the fields of

generator or on the storage batteries. The duty of the motor generator when in use is to maintain on an alarm circuit a current of .04 ampere. The current in the fire alarm circuit can evidently be adjusted in a number of ways by the arrangement of apparatus shown. The current around the fields of the gen-

FIG. 1.—DIAGRAM OF CONNECTIONS FOR MOTOR-GENERATOR PLANT OF CHICAGO FIRE ALARM SYSTEM.

erator can be varied, the speed of the motor can be changed by varying the motor field resistance, or finally an adjustable resistance in the fire alarm circuit itself can be used to regulate the amount of current flowing in the fire alarm circuit.

Six motor generators have been put in. One of these gives 100 volts for the alarm circuit, two give 70 volts, and three give

FIG. 2.—SET OF MOTOR GENERATORS, CHICAGO FIRE ALARM SYSTEM.

both machines are connected directly across the mains of the 110 volt supply circuit. The speed of the motor is varied by an adjustable resistance in its field circuit. The field circuit of the generator is also provided with a variable resistance. From the armature of the generator, to which the fire alarm circuit is connected, the circuit runs out through the various street alarm boxes and back through a relay in the central office to the motor generator. The office apparatus which the relay operates does not now concern us. The double throw switch is for throwing the fire alarm circuit either on the motor

40 volts. Thus six different circuits are supplied. The motor generators were supplied by the Western Electric Company. They have been in continuous operation since they were put in, and, except when the storage battery is being "exercised," will probably be used most of the time.

NEW CABLE STEAMER. The largest cable steamer afloat has just been launched in England for the Telegraph Construction and Maintenance Co., Ltd. She is 465 feet long over all, and has four huge cable tanks. She is called the "Anglia."

The "American" Electric Motor Vehicles.

IN view of the rapid strides which have been made in the development of automobiles in this country and the interest which is being manifested in the art by inventors, scientists and the public in general, it would appear as if we were on the eve of a great industrial revolution along the lines of road transportation. Each week brings forth new developments, more efficient motors and simpler mechanisms; and the existing competition along this promising line must certainly be productive of splendid results. Regarding the motive power it appears as if electricity, the most subtle, adaptable and elastic force known to engineers, will beyond a doubt triumph as the ideal agent for carriage propulsion.

We are pleased to note the energy with which companies are pushing to the front vehicles using electricity for a motive power and the success with which they are meeting. One of the first companies to begin the manufacture of electrically propelled vehicles are the Indiana Bicycle Company, of Indianapolis, Ind., who are now putting on the market their splendid line of American electric motor vehicles, a number of which are illustrated herewith. They are the outcome of experimental

FIG. 1.—RUN-ABOUT, $1\frac{1}{2}$ H. P.

work conducted at a cost of more than \$150,000, which has resulted in the production of a simple, comparatively light and most practical machine for pleasure or business, a machine of high efficiency, economically and easily operated and entirely free from objectionable features.

The carriages are constructed throughout in the most thorough manner from carefully selected materials, and are designed to withstand continuous hard service under the most trying conditions. The frame work of the running gear is tubular, with large, strong connections carefully brazed at each joint, the whole designed to resist all strains likely to be put upon it. The tubing is cold-drawn and seamless, of highest grade manufactured. All wheels have ball bearings, those for the lighter types of carriages being wire spoked and having Royal single tube pneumatic tires, the heavier vehicles having wood spokes and cushion tires. The running gears are made in three sizes, with the slight variation in design necessary to adapt them to the variety of vehicles.

The motor is of the multipolar type, brought to the latest and most efficient practice and carefully designed for its special purpose, with due regard for overloads and having a reserve capacity sufficiently large to insure it against accidents. It is rigidly hung to the frame of the running gear and it and all gears are carefully covered, amply protecting them from dust and water so that in cleaning the carriage only moderate care need be exercised.

The motor shaft is geared directly to the two rear wheels, propelling the vehicle by a single reduction. Each rear wheel

is made to revolve independently of the other by compensating gears placed in line with the motor shaft. Motors are made in three sizes of one and one-half, two and one-half and three

FIG. 2.—MAIL PHAETON, $2\frac{1}{2}$ H. P.

and one-half horse power each, according to the weights of the vehicles.

The batteries, said to be covered by broad and original patent claims, are of a new and distinct type, and are claimed to be of less than one-half the weight of the usual storage cells used in other wagons of the same capacity. The battery consists of forty-four polarization cells varying in size from 60 ampere hour to 125 ampere hour capacity according to power desired, the weight of the lightest being about nine pounds for each cell. These are placed in four trays of eleven cells each. The normal discharge rate of the battery is about fifteen amperes, at which rate of discharge the wagon runs at a speed of from twelve to fourteen miles per hour. A wattmeter attached to the battery is conveniently placed for observation. This meter registers the amount of power in watt hours going out of the battery and into the motor, enabling the operator to see at any time at a glance the amount of energy in store.

The charging can be accomplished by connection with any direct current lighting circuit. An automatic device closes the switch when the batteries are full. Where a number of electric vehicles are used, like delivery wagons, etc., a small private generating plant is desirable and the company will soon be prepared to furnish such an equipment at moderate cost.

A simple ratchet lever set on notches for starting the vehicle, regulating its speed, etc., is placed at the extreme left side of the

FIG. 3.—DELIVERY WAGON, $3\frac{1}{2}$ H. P.

seat and actuates a controller placed beneath the seat, controlling the amount of electricity flowing from the batteries to the motor. The first or slowest speed is obtained by grouping the

four trays in parallel; the second or medium speed by grouping two trays in parallel and two in series; the third or highest speed by four trays in series. The current delivered to the motor for each of the speeds is practically constant, but the speed of the motor and the current delivered from each tray of batteries vary directly with the voltage, thus making the consumption of energy at all times proportional to the speed. The controller contacts are sliding and self-cleaning and so constructed that destructive arcing or burning at these points when shifting the speed circuits is entirely prevented. The carriage is reversed by a key placed directly below the controller, the turning of which simply reverses the polarity of the armature.

FIG. 4.—BROUGHAM, $3\frac{1}{2}$ H. P.

The removal of this key makes the vehicle inoperative so that it can be safely left alone anywhere without danger from willful or accidental tampering through curiosity or malice.

The steering is accomplished by a lever conveniently placed and is a very natural movement requiring practically no exertion and needing no particular explanation. The radius of turning is done with a very small amplitude of lever movement and the small wagons can be turned completely in an alley-way fifteen feet wide. A band brake is applied to the periphery of the compensating gear drum and is operated by a pressure of the foot upon a stem projecting through the floor of the vehicle. This brake is very powerful and will stop a vehicle in about its own length at full speed, or reduce its speed gently if applied gradually.

The carriage bodies are made from the best seasoned stock, thoroughly put together, and braced and ironed in the most approved manner. They are of modern design and extremely graceful in appearance. They are furnished to correspond with the highest type of vehicles in use and careful attention is bestowed upon the elegance and comfort of the upholstery, lighting and fitting generally. In its every appointment, the "American" will favorably compare with any high class equipage for park or business use.

In Fig. 1 is shown the "runabout" of $1\frac{1}{2}$ h. p. capacity, costing \$1,000. A "mail phaeton" is shown in Fig. 2, its motor developing $2\frac{1}{2}$ h. p. and costing \$1,500. In Fig. 3 is shown a delivery wagon, of $3\frac{1}{2}$ h. p. and costing \$1,800. It may be of interest to present a table showing the comparative first cost and cost of maintenance of this vehicle and an ordinary delivery wagon drawn by a horse:

First cost horse power delivery wagon.....	\$250
Two horses.....	250
Harness	75
Stabling, feeding, shoeing, veterinary service, etc., two horses at \$25 per month for three years.....	1,800
Wages of extra boy with driver, at \$25 per month.....	900
Total	\$3,275
Electric vehicle, first cost.....	\$1,800
30 miles per day for three years, or 27,000 miles at 1 cent per mile.....	270
Total	\$2,070

Assuming that repairs will be about equal, this shows a large saving in favor of the electric vehicle. As to the above estimate, attention should be called to the fact that the wages of the driver are omitted in both cases as it is an expense common to both wagons.

In Fig. 4 is shown the "Waverly Brougham" of $3\frac{1}{2}$ h. p., equipped with 44 cells of 120 ampere-hour capacity and costing \$2,500. This vehicle is small and light, and is suitable for either business or pleasure. It is a stylish carriage with removable rear seat, and is designed for equipment with electric heater, if desired. The company are prepared to accept special orders and submit designs for approval and their guarantee, which has become of great value on account of the reliability of the company's products for many years, accompanies every vehicle they manufacture.

A Plea for the Introduction of Goods Traffic on Our Suburban Trolleys.

BY W. T. BONNER, MONTREAL.

THE first consideration in exploiting any new suburban tramway is the possible or available passenger traffic. That being found inadequate to guarantee a fair return on the cost of installation and maintenance, the project is usually abandoned for the reason that only passenger traffic can be considered, owing to the high cost of handling goods traffic at the terminals. While a motorman and conductor are sufficient to handle a two or three-car electric train for passenger traffic, with very little expenditure of time or assistance for loading and unloading, all railways under present systems require a large additional force to conduct the hundreds of details attending the reception, checking, loading, transferring, unloading and proper delivery, in good order, of either car lot or package freight.

It is not the railway investors alone who suffer the effects of this handicap, but the property owners also, since the latter have no recourse, while the capitalist has but to seek other more profitable fields for investment.

It may therefore be conceded that the whole subject presents two phases of commercial economy, viz.:

(a) From the standpoint of the agriculturalist and land owner; how best to provide a means for increasing the value of remote but otherwise valuable agricultural lands, and at the same time retain present value of adjacent property by converting it from market gardens into residence and manufacturing sites.

(b) From the standpoint of the capitalist and manager of railway properties; how best to increase the earning capacity of existing or proposed suburban lines.

With the ever increasing centralization of population and commerce, inaccessible property becomes less valuable; all land,

FIG. 1.

whether barren or fertile, suffering alike, according to its distance from the centre of demand for farm products, which we call markets. Such distance is not always measured in actual miles, but rather in accessibility, since in our day we find frequent examples of the paradoxical long and short haul rates. The Minnesota and Manitoba farmers will deliver their wheat at the seaboard at a lower cost per bushel than the farmer who may live a hundred miles off the coast. The Eastern farmer may have just as fertile land as his Western competitor, but he is handicapped by having to haul his wheat forty or fifty miles over poor wagon roads to reach the nearest railroad.

In either case, the terminal charges, including the cost of load-

ing the produce at the farm, is approximately the same, but the difference in cost of haulage per ton-mile by railroad and wagon road is so tremendously in favor of the former that without such facilities the farmer may as well retire from business. It has been stated as a fact that to transport a ton of coal from Buffalo to Chicago costs no more than to move the same quantity of coal across the sidewalk in either city.

In a late number of the "Marine Review" some interesting comparisons were made between the present cost of shipping coal to the Northwest and prices which obtained previous to

FIG. 2.

the introduction of modern vessels and automatic coal handling machinery. Car-dump machines can now load four thousand tons in ten hours, as compared with two or three days under old methods; and coal is now carried from Lake Erie ports to the head of Lake Superior at twenty cents per ton, as against fifty cents, which was considered a ruinously low rate a few years ago.

It is frequently asserted that since the introduction and development of steam railways, they have gradually superseded the earlier methods of transportation and traffic, and as a consequence highways are no longer an indication of progress. This is true only to a limited extent. Railroads have changed the character of suburban traffic, and personal travel is no longer dependent upon the condition of the highways, but commercial intercourse, as represented in the exchange of products, is as much dependent upon the condition of the public road to-day as it ever was, for the reason that it is impossible to construct a railroad to the door of each producer and consumer. Hence railroads can never entirely supersede the common road, and every ton of freight carried by them must be conveyed over a highway at either or both terminals, and the cost of this highway transportation has a marked influence, not alone upon the price paid by the consumer, but also on the profit realized by the producer.

Few people have any knowledge of the real cost of transportation by horse and wagon, or comprehend the amount of money expended needlessly every year through failure to provide proper roadways and modern tramways.

The following table shows the results of actual observations on the cost of moving a load of one ton a distance of one mile on level roadways, with different pavements and under average conditions:

TABLE I.

COST OF TRANSPORTATION BY HORSES AND WAGONS PER TON-MILE ON DIFFERENT SURFACES.

	Cents per ton-mile.
Iron rails	1.28
Asphalt	2.70
Stone, paving, dry and in good order.....	5.33
Stone, paving, ordinary condition.....	12.00
Stone, paving, covered with mud.....	21.30
Broken stone, dry and in good order.....	8.00
Broken stone, moist and in good order.....	10.30
Broken stone, ordinary condition.....	11.90
Broken stone, covered with mud.....	14.30
Broken stone, ruts and mud.....	26.00
Earth, dry and hard.....	18.00

Earth, ruts and mud.....	39.00
Gravel, loose.....	51.60
Gravel, compacted	12.80
Plank, good condition	8.80
Sand, wet	32.60
Sand, dry	64.00

The comparative cost of transportation over rough roads may be estimated from Table No. 2, which shows with sufficient exactness for most practical purposes, the force required to draw loaded wagons over inclines. This table shows the force exerted by the load in its downward tendency, as well as the force required to draw it up grades of various inclinations; also maximum duty performed by an average horse, weighing, say twelve hundred pounds, the friction of the surface being taken at one-fiftieth of the load drawn:

TABLE II.

Rate of grade, ft. per 100 ft.	Pressure on the plane in lbs. per ton.	Tendency down the plane in lbs. per ton.	Power in lbs. required to haul one ton up the plane.	Equivalent of inclined road, miles.	Max. load in lbs. which a horse can haul.
0.0	2240	.00	45.00	1.000	6270
0.25	2240	5.60	50.60	1.121	5376

2.50	2240	56.00	101.00	2.244	2725
2.75	2240	61.33	106.33	2.363	2620
3	2239	67.20	112.20	2.484	2486
4	2238	89.20	134.20	2.982	2083
5	2237	112.00	157.00	3.444	1800
6	2233	134.40	179.40	3.986	1568
7	2232	156.80	201.80	4.844	1367
8	2232	179.20	224.20	4.982	1235
9	2231	201.60	246.60	5.480	1125
10	2229	224.00	269.00	5.977	1030

From the foregoing tables, and from statistics gathered by both State and national bureaus, it has been calculated that the average cost of transportation by animal power is twenty-five cents per ton per mile. Furthermore, the rate of transportation by animal power is, and always has been, excessively high, and

FIG. 3.

the evidence of all statistics, both ancient and modern, shows but slight improvement as compared with the progress made in other departments of industry, and by other means of transportation. It being true that the value of land and wages of labor are affected by the cost of transportation, we should expect to find that where so high a rate as twenty-five cents per ton-mile prevails, the land would diminish in value, and the rewards of labor bestowed upon such lands would grow less and less. What we expect to find, we do find.

A forcible illustration of this fact was brought to the writer's attention a few days ago. A resident of Long Island, living

about fifty miles out from New York City, owns 500 acres of as fertile land as may be found anywhere. Although beautifully situated, and with every natural advantage to favor production, the cultivation of all staple products has been abandoned by him owing to lack of proper transportation facilities. With potatoes jobbing at eighty cents to one dollar per bushel in New York, he was compelled to sacrifice his entire crop, giving away hundreds of bushels, rather than allow them to rot in his cellars.

It is not necessary for the careful observer to rely solely upon official reports for information, for the above is but an every-day example of the result of excessive cost of transportation, the ever-decreasing price of inaccessible land, and the diminished rewards of labor bestowed upon it. The price of land and the value of labor decreases in almost inverse proportion to the distance over which the agricultural products must be transported by horse power.

One fact is patent to all, that whereas formerly the distribution of population was approximately equal over the face of the country, it is gradually becoming concentrated into large cities to such an extent that already fully one-half of the inhabitants of the older sections of the country live in cities. The evident reason for this is competition, the demand for increased output at reduced cost. Concentration indicates increased power for production. Take, for instance, some of our commonest staples, like wheat, beef, pork, molasses, wagons, horseshoes, butter and clothing. Within the writer's memory, these articles were produced at home, or in small shops and factories distributed, like the population, quite equally throughout the country at cross-roads and villages, utilizing crude methods and operated by the old-fashioned treadmill or horse power, and overshot water

FIG. 4.

wheels. The output of flour per man per day in those mills did not exceed ten barrels. At the great Winnipeg and Keewatin mills and at Minneapolis the milling business has been so concentrated that to-day the output per man exceeds one hundred barrels and the cost of production is correspondingly reduced. But of what benefit to inaccessible property in the interior is this reduced cost of production, unless like facilities for transportation are afforded?

The measure of benefit which any improvement in production in one community bears to another community, depends entirely upon the transportation facilities between the two places. Recently a customer came into our office from one of the interior mining plants. We estimated the plant he required would cost \$1,255. To help him out all we could, we eliminated every possible item not absolutely essential to the proper working of the plant, and allowing also for erector not being required, we found we could reduce our price 10 per cent., making the net total \$1,130. But how insignificant our discount appeared when we learned the freight from Montreal to the mine would cost \$1,248, notwithstanding no part of the route required mule-back transportation. Although further distant from Montreal, the same plant could be transported to Vancouver for less than \$250.

Concentration of population and production requires for the better equalization of supply, and price of materials and provisions, that such centres must be provided with commercial veins and arteries which shall quickly and cheaply transport or

exchange urban and suburban passengers and commodities. While long haul rates of transportation by railroads and steamships have been wonderfully cheapened, there still remains a space of fifteen to twenty-five or even forty or fifty miles surrounding every commercial centre, which has never been covered by any cheap method of transportation. Such distances are beyond the possibility of cheap or efficient service by animal power, and the terminal charges and bulky plant required, preclude any possibility of much reduction in railroad tariffs.

FIG. 5.

What we require therefore is a new system of transportation which shall be alike available for freight and passengers.

The problem of handling exclusively passenger traffic is comparatively simple; indeed, it has already been solved for those districts where the population is sufficiently dense to support steam or electric tramways requiring no other source of revenue. Experienced railroad men are unanimous, however, in agreeing that no road, whether steam or electric, will pay in a thinly settled district unless assisted by a bonus or by the addition of freight traffic.

In this day of great competition capital is constantly seeking methods for reducing costs. Manufacturers calculate even the individual bristles required to make a brush, and the ounces of warp in a yard of cloth. An extra hair in a brush or an ounce of warp more than is necessary, does not amount to much in a single brush or a yard of cloth, but the savings in a day's output might make a perceptible increase in the dividend account. Cost of operation and maintenance are to-day the great factors in every commercial or manufacturing calculation. Capital is ever ready to supply the installation provided it can be insured a fair return on the investment.

In 1894 the writer promoted a scheme for uniting one of the large commercial centres on Lake Erie with several surrounding counties by a system of electric railways which would combine both freight and passenger traffic. The arrangement was such that the farmers anywhere along the line would secure the immediate benefit of the higher city market rates for their produce, as well as competitive selection and prices for supplies. Local and sub-stations were to be established at frequent points along the line where the farmers could deposit their produce to be forwarded by next train to a central clearing house in the city from whence it could be delivered at once to the consumer. The scheme was to be co-operative in a measure, the

FIG. 6.

subscribers to receive the first benefits. Telephone connection was to be established between the city and farm residences through the company's local stations, and direct orders for goods from the city merchant could be received by wire and despatched by next train out. Only samples, or a very limited supply of staple goods, were to be kept at the local stations,

the principal stock to be maintained at the central clearing house, and by the various city merchants who belonged to the syndicate. Electric current for light and power was also to be supplied to consumers along the line. In short, it was proposed to so unite city and country by wire and rail that all would enjoy equal facilities for obtaining supplies.

Unfortunately the financial depression of that year so handicapped our efforts that we were unable to carry out the project, but those who gave the subject most careful consideration at the time still expect to see some such system as the above in general use.

The latest development in the line of providing for goods traffic on electric tramways came to the writer's notice some months ago in the shape of a combination vehicle, so constructed as to be readily convertible for use upon any ordinary roadway or upon a railroad track. It can be shifted from one to the other at will, without the necessity of reloading or rehandling the contents between points of shipment and destination. The idea is not altogether new, but the application will no doubt impress you all as novel in the extreme.

The Bonner Rail Wagon Company, organized about a year ago to develop the patents of Col. Jos. C. Bonner, of Toledo, O., states in its prospectus that it will build rail wagons and operate them through leases or franchises granted to interurban electric railroads. It is proposed that such roads shall be equipped with any stipulated number of rail wagons, thus enabling them to supply patrons at any point along their lines, or at the terminal stations.

The general supervision and control will be vested in the Rail Wagon Company, thus relieving the local electric railways of the detail inspection and repairing, as well as freight contracting. The Wagon Company will contract to provide service as the traffic of the electric roads may require. The wagons will be neat and substantial and tarpaulin-covered at all times, whether loaded or not, after the same manner as the goods vans are covered on English and continental railroads. This provision permits sealing and also provides protection against exposure to inclement weather.

As an essential feature of this enterprise, the Rail Wagon Company will supply horses and drivers for service at terminals, thereby retaining in responsible hands, the execution of traffic agreements, and establishing a direct-connecting link between the producer and the consumer. Agents will collect the freight charges, which charges will include delivery to consumer. The tariff rates, covering both freight and delivery, will naturally be much less than prevailing freight charges under old methods of transportation, since no allowance need be made for capital invested in expensive terminals or for maintenance of same.

Fig. 1 of the annexed cuts illustrates the integral parts of the combination vehicle. The wagon proper is patterned after the ordinary improved road wagon, modified, of course, for the special nature of the service contemplated. The running gears and springs are of standard construction having a carrying capacity of from three to seven tons, depending upon the class of freight to be carried.

The rail truck is not materially different from the car truck in general use upon our electric railways, except that it is provided with special attachments for automatically gripping and supporting the wagon proper. The truck is exceedingly simple in design and very light in proportion to its strength, being constructed entirely of wrought iron and cast steel.

Fig. 2 shows more clearly the detail construction of the rail truck and the arrangement of the cast steel segments or dogs, supported in place horizontally by heavy plate springs, and used for the purpose of engaging the axles of the road wagon as the truck approaches from either direction.

Fig. 3 shows the road wagon in position on the loading switch with rail truck underneath, the dogs engaging the axles, ready to pull ahead. As the truck is drawn forward on the level rail by the electric motor, the impact of the projecting dogs against the wagon axles also starts the wagon forward, and as the latter travels down the inclined switch track, the axles gradually settle into the notch provided in the cast iron journal frames.

Fig. 4 represents the wagon mounted on rail truck standing on the open track ready to be coupled to a motor car, or electric locomotive. Fig. 5 illustrates a train of five wagons, drawn by an electric locomotive en route across the country, while Fig. 6 represents several rail wagons side tracked in convenient

market stalls, the commission agent or owner serving out the contents fresh from the farm.

The actual time required for unshipping the wagon from the truck for road use, and vice versa, is not more than would be required for coupling together cars in making up a train.

The weight of the combined wagon and truck is sufficient to insure perfect rail traction and the proportions between carrying capacity and dead weight averages about the same as the ordinary freight car.

By establishing a uniformity of dimensions and making the rail truck interchangeable, the wagons can be loaded either end on from either direction, and any number of rail wagons can be connected and moved in either direction as a train, by steam, electric or other motive power.

The farmer or merchant need have no ownership in the rail wagons. On a signal or other notice to the electric railroad, a rail wagon may be placed on a convenient farm switch or siding. The farmer readily unships the wagon from its rail truck by simply hitching his horses to the wagon and driving off, leaving the rail truck to remain where it stands until he returns with the wagon loaded for market. Convenient receiving and distributing stations can be located in the cities. Bulk merchandise can be handled; parcels, mail and express matter also, the rail wagon making store to store collections or deliveries. The movement of these road wagons need not in any way interfere with passenger service of the electric railways, the heavy traffic being carried at night, when the electric lines and streets are least in use.

The great value of this novel method of handling goods traffic is readily demonstrated. Not only does it insure economy of time, labor and expense by avoiding reloading in transit, but the reduction in breakage which usually attends the shipment of eggs, glassware, pressed brick, or other fragile commodities, guarantees for it preference over other systems of transportation.

With these changed conditions of suburban traffic the greater part of the haul would be by rail, consequently the weight of the load units can be greatly increased. A team of horses can exert, for a short period, twice the average tractive pull which they would be able to exert continuously throughout a day's work, and, so long as the resistance on the incline is not more than double the resistance on the level, it follows they would be able to draw over short hills the maximum load they are capable of drawing along a level road.

Such a system as the above would at once render accessible endless acres of fertile interior lands, and open them up to the systematic energy of the thrifty market gardener, the dairyman and the fruit grower. Improved conditions would result to the truck farmer, who would no longer be obliged to spend his night in long weary drives in order to reach the early market. Instead, his day's harvest would be transported to town during the night by electric rail wagon while man and horse refresh themselves in sleep.

Thus would we increase the market value of distant agricultural lands, and at the same time retain present values of nearby property. With the increase of land values and production, must also come increased traffic for existing or proposed suburban railways.

Large Railway Storage Battery Plants for Chicago Elevated Railroads.

Mr. Frank H. Clark, manager of the Chicago office of the Electric Storage Battery Co., reports that they have just closed a contract with the South Side Elevated Railroad, of Chicago, for two electric storage batteries for about 700 horse power each; one to be installed in a sub-station on their property at Twelfth street, and the other in a sub-station on their property at Sixty-first street. Each battery will be provided with tanks and bus-bars of suitable size for doubling the capacity of the battery. The batteries will be placed in parallel with the line, and so arranged as to take care of the maximum fluctuations, relieving the power house of a portion of its load, and at the same time keeping up the potential at the extreme points on the line. This will be the largest installation that has yet been made for feeder regulation, so that when completed, Chicago will have the largest central lighting station battery and the largest feeder regulation battery installation yet installed, the central station plant being that of the Chicago Edison Co.

Power Consumption in Electric Railroading.—I¹

BY S. T. DODD.

I SUPPOSE there are several here to-night who will appreciate my feelings when one day, about ten years ago, I visited the city of Boston and there saw an electric street car propelled by the power of forty horses. To my mind, acquainted only with ordinary two-horse traction, a double 20 h. p. equipment seemed out of all proportion to the speed and size of the car.

Our ideas on such subjects have changed since those days, and to-day no one would think of using less than a double 25 h. p. equipment for street railway work, while double and quadruple 25, 50 and even 75 h. p. equipments are so familiar that they pass through our streets without comment.

I do not suppose any member of this club would expect to operate a 20-ton car at a speed of thirty miles per hour, with the current it takes to run an arc lamp, yet such a mistake would be no more glaring than some that have been made in the development of electric traction. What I propose to do to-night is to attempt to make an analysis of the losses occurring in electric railway operation and to show that the power of our equipments is no greater than might be expected upon the ordinary laws of mechanics, from the weights we are propelling and the speeds, acceleration and grades which we encounter.

The power necessary for propelling a car or train is equal to the product of the quantities: the speed, which is a quantity,

FIG. 1.

definite, measurable and easily recognized, and the force, the effort exerted by the motive mechanism, or its equivalent the train resistance. The latter being more obscure and less easily measured, deserves a careful study.

In analyzing the train resistance, four principal divisions must be noted: (1) Grade resistance or the effort necessary to lift a train up a certain slope. In electric railroad work this becomes a more important factor than in steam railroad work, on account of the steeper grades we encounter.

(2) Curve resistance, or the effort necessary to propel the cars around curves upon the track. This enters in as such a small factor that I shall only note it here for the purpose of completeness and shall not refer to it again.

(3) Acceleration resistance, or the effort necessary to carry a car of a given weight to a certain velocity in a certain time. On account of the character of the traffic in electric railroad work this becomes a more important factor than it is in steam railroad work.

(4) Frictional resistance, or the effort necessary to propel a train at a constant velocity over a level track. This division being the most obscure shall receive our attention first.

FRictional RESISTANCE.

The nature of the resistance encountered by moving trains has been discussed by steam railroad engineers for many years.

I might stop here to note an advantage which we have in electric railroad work over steam railroad engineers in the measurement of this quantity. In steam railroad work readings from a dynamometer interposed between the engine and train only give the resistance of the train itself, leaving out of account the resistances experienced by the engine, which, in many cases, amount to a very considerable proportion of the whole. While the reading of steam engine indicators is a sufficiently laborious and delicate operation on stationary engines, it is much more so when the position of the observer is on the outside of a locomotive running at 25 to 60 miles an hour, and even with this indicator reading, unless the efficiency of the engine is very accurately known, as it seldom is, we are unable to separate the quantity, train resistance, from the internal losses in the engine.

On the other hand, the determination of this quantity in electric railway work is a very simple matter.

Fig. 1 represents the curves of torque and speed of a street railway motor. These curves can generally be obtained from the manufacturer of the motor; or if necessary, their independent determination is a very simple matter. The perpendicular height of any point on either curve represents the current flowing into the motor, while the horizontal distance from the left hand side of the sheet shows upon one curve the speed in miles per hour at a fixed voltage and upon the other curve, the horizontal effort in lbs. which the motor will exert at the tread of the driving wheels when it is taking this amount of current. In order to determine the effort exerted by a car equipment, it is only necessary to place an ammeter in circuit with the motors, and the reading of this by comparison with the curves of the particular motor gives us immediately the horizontal effort exerted by the motor at that instant and, approximately, the speed. For example, supposing the motor in question is geared with 24 teeth in the pinion and 58 teeth in the axle gear, the two curves marked "Gearing 58/24" in Fig. 1 show that when 30 amperes are flowing into the motor it will exert a horizontal force at the rim of 33-inch driving wheels of 120 lbs. and the car will be moving at 42 miles per hour with 500 volts at the motor terminals. If the ammeter reading is 125 amperes the same curves show that the effort exerted is 1,320 lbs. and the speed is 17.5 miles per hour. I say "approximately the speed" because the speed is dependent upon and almost proportional to the voltage at the motor terminals, and as this fluctuates in electric railway work anywhere from 10 to 20 per cent. the speed cannot be determined without a simultaneous determination of the voltage. The torque exerted by the motors, however, is independent of the voltage; a certain current flowing through the coils of the motor will develop a definite pull at the armature shaft. I am aware that this statement contradicts a popular impression that a series wound motor will take more current to drive a car at a low voltage than at a high, but it can be shown that the statement is absolutely true, and that the popular impression is the result of mistaken, or rather, misinterpreted, observations.

Electrical Canal Traction in Europe.

A French company have just requested the French, Belgian and Dutch governments to allow them to establish along the navigable rivers and canals in these three countries a system of electric traction, in order to form an international network of electric towage, which will stretch from the Rhine, in Holland, to Marseilles, through the eastern provinces of France. Several canals in the north of France are to be connected with the Upper Meuse. It is urged that when this project is realized a great and probably favorable influence will be exerted upon the French and Belgian coal mining industry.

ROME, ITALY. The Electricitäts-Gesellschaft Felix Singer & Co. Act.-Gesellschaft has been recently given an order by the Società Romana Tramways Omnibus at Rome for the electric equipment of 30 motor cars, each with two Walker motors. It may be noticed that this order was given after experience with the Walker material in trial installations.

THIRD AVENUE ROAD has permission to change its motive power to electricity on the cable routes, but the Railroad Commission withholds its present consent as to use of compressed air or of storage batteries. When the company is ready for these, it can ask again.

The 1898 Report of the Detroit Municipal Electric Light Plant.

THE Public Lighting Commission of the city of Detroit has just published its report for 1897-8, on the working the city lighting plant, and appears well satisfied with its work, although "the results from labor will not compare as favorably, for the reason that slightly higher wages are paid and much shorter hours of work are obligatory." The Commission has reorganized its staff to get the most work out of it under the conditions. Each trimmer now has from 59 to 74 lamps on $7\frac{3}{4}$ miles of average circuit, the trimmer walking, and then doing no further work. We quote in extenso from the report as follows:

"By these economies the Commission was able to reduce the cash outlay per lamp from \$64.19 per annum for a monthly average of 1,564 lamps for the preceding year, to \$51.85 per annum for a monthly average of 1,744 lamps. The reduction was largely in the item of labor, being reduced from \$43.57 per lamp to \$33.27 per lamp, while the reductions in the cost of supplies was from \$20.62 to \$18.58 per lamp.

"To arrive at the cost of an arc lamp to the city of Detroit per annum, there should be added to the above cash cost of \$51.85 a certain amount for interest on the investment, for loss of taxes through the plant not being owned by private parties and for depreciation. The first two items are easily computed, for the average investment for the year was, in round numbers, \$750,000.00 with interest at 4 per cent, and the assessed value of the same was placed by the City Assessors at \$400,000, with the rate of taxation at \$17.68 for the City and at \$3.24 for the State and County, a total tax of \$20.92 per \$1,000; but with the latter, that is, the figuring of the depreciation, there is a wide difference of opinions. As per the statistics published by the "London Electrician," of England, it is customary for the municipal lighting plants of that country to set aside annually about three per cent. of the entire investment as part of the expenses for a sinking fund. The writers on the subject in scientific journals in the United States have ranged from 3 per cent. to $7\frac{1}{2}$ per cent. as the amount to be charged off for depreciation or for a sinking fund. This Commission held in its preceding report that a plant established and maintained similar to the Detroit City Plant should not be subjected to a heavy expense item for depreciation or a sinking fund. The Commission held that only a "wear" depreciation should be charged, and then only on such parts (as boilers) which, after a period of time, would have to be changed as an entirety. As a compromise, however, the Commission takes the rate of 3 per cent. to set aside with the cost of a lamp per year for a sinking fund or depreciation, and the reader may change that rate as per his pleasure. Computing these fixed charges we have:

Interest at 4 per cent. on \$750,000 average investment.....	\$30,000
Depreciation at 3 per cent. on \$750,000 average investment.....	22,500
Taxes at \$20.92 on \$400,000 assessed valuation.....	8,368

A total of.....\$60,868

"Proportioning this on the basis of the electrical output and we have \$55,207.27 chargeable to arc lighting, or \$31.65 per annum per arc lamp. The total cost of an arc lamp to the City of Detroit per annum on these figures may, therefore, be placed at \$83.50.

"In February, 1893, the Detroit Electric Light & Power Co. offered to light the City of Detroit for a period of ten years at the rate of \$102.20 per arc lamp per year. While there are no recent bids available from which the exact cost to the City of an arc lamp by commercial companies may be obtained, it is entirely reasonable to presume that in common with all other industries, the cost per lamp has been reduced at least 10 per cent. during the interval of five years which has elapsed. The cost, therefore, at present may be assumed to be not greater than \$90 per arc lamp per year. For a number of reasons it is believed

that the rate of \$90 per year is a conservative figure which may be justified.

"Taking that assumption as correct, it will be seen that the amount per arc lamp which the City has saved during the past year, after allowing the 3 per cent. for depreciation, as compared with the cost of the same lamp by a commercial company, was something less than \$7. This narrow margin, the Commission believes, fully justifies its course in reducing the expenses during the past year to the lowest minimum possible consistent with the best service and the limiting conditions under which a municipal plant must always be operated.

"While it is possible that improvements in some machinery may be made soon, which would cause a partial loss to the city of the value of part of its investment in machinery, on the other hand it is only fair to state that there is an equal probability of compensating improvements in other devices and which will enable the City to further reduce the cost per lamp per year. Reductions in cost, due to such improvements, of course would not accrue to the City if it already had a lighting contract extending over a period of years.

"The ultimate success of the plan of municipal ownership of a public lighting plant, viewed from the standpoint of economy to the taxpayer, can not as yet be claimed to be assured in the City of Detroit. Time is an essential element of consideration in arriving at a judgment at all valuable upon this question. The plant, the business of which we have the honor to administer, has been in existence since April, 1895, but it is only since November 1, 1897, that the construction feature of our business was completed and the plant placed upon a purely operating basis. This period is entirely too short to justify absolute conclusions as to the ultimate success of the municipal venture from an economical view.

CHART REPRESENTING PERIODS OF ARC LIGHT BURNING AT DETROIT, MICH.

"The margin of profit per lamp at the present time, while it is not large, nevertheless is a showing to the advantage of the City, which it is to be hoped will be maintained or increased in the future. It is but just to observe in this connection that the quality of light furnished has been uniformly of the full standard of 2,000 candle power, which is better than was found practicable to obtain of contractors; and also that collateral advantages not easily reducible to terms of pecuniary value have accrued to the City by reason of its operation of its own lighting plant. The results, such as they are, have been secured by the Commission only by the practice of the strictest economy and the rigid exclusion of all of those elements so apt to intrude into the administration of public municipal affairs, and which operate only to confound business principles and political expediency in perplexing entanglement. It has not been at all times easy to persuade some that these two policies occasionally clash irreconcilably, and, in the determination of the one or the other to be followed, it was the duty of the Commission to be guided solely by the interest of the taxpayer."

Annexed to the report and its financial details are a number of handsome illustrations of the plant, and one interesting diagram, which shows the distribution of lighting through the year. The diagram is reproduced herewith.

COMMISSIONER KEARNY will try 500 Welsbachs in street lighting in Brooklyn. We refer him to the report of City Superintendent of Lighting, Mr. Hopkins, of New Haven. The results are all there.

SANTIAGO DE CUBA having surrendered is returning to the ways of civilization. The electric light plant has been put in operation again.

Vol. XXVI. NEW YORK, AUGUST 18, 1898. No. 537.

The Detroit Municipal Lighting Plant.

FROM time to time we have had occasion to note the annual and ad interim reports of the Detroit municipal electric light plant; and we are now in receipt of the third annual report coming down to June 30, 1898. It will be found copiously abstracted in the present issue of The Electrical Engineer, and is certainly a document to be read and studied with a good deal of interest. The plant at Detroit is one on which great hopes were founded, and is one upon which many arguments for city ownership have been based. The conditions were all favorable. Well selected apparatus was carefully installed, and the Commission appears to have consisted of business men of public spirit. The plant has been on a large scale, and has thus enjoyed the opportunities for steady load and close economy, not presented by plants on a smaller plan of operation. In other words, the showing should be excellent in Detroit if anywhere.

Now, what does one find? An excellent showing, we will admit, but how different from all the terrific claims of saving to be effected by this investment of public money! The report says distinctly that with a depreciation allowance of only 3 per cent., which is grotesquely inadequate, "the total cost of an arc lamp to the city of Detroit may be placed at \$83.50." It is admitted that, as far back of 1893, the Detroit Electric Light and Power Co. offered to do the lighting for ten years at \$102.20 per lamp. Figuring that in five years, the cost from private companies has fallen only 10 per cent., when as a matter of fact it is often 20 and 25, the report claims that it is saving the city "something less than \$7 per lamp." That is, with depreciation at only 3 per cent., no allowance for water that we can detect in the accounts, and no allowance for a general proportionate share in the running expenses of the city government (for each city department ought to be debited with a certain proportion of all general city expenses) the plant saves the city about \$12,000 a year. We do not believe, and we cannot admit under such circumstances that the municipal plant saves the city of Detroit a single cent of the alleged saving. It is not there.

In fact, the report itself says: "The ultimate success of the plan of municipal ownership of a public lighting plant, viewed from the standpoint of economy to the taxpayer, cannot as yet be claimed to be assured in the city of Detroit." Yet the Indianapolis "News" has the audacity to claim that the Detroit plant has reduced the cost of lighting to \$51.85 per lamp, "being less than one-half what the city formerly paid to private corporations," and the St. Paul "Pioneer-Press" and other papers actually reprint such wild inaccuracies as an argument for municipal ownership. There is the report. Why do they not print it or read it?

That is the rub. Such reports, made by the friends of municipal ownership, only prove the contentions of those opposed to commercial investment of money raised by city taxation. We do not wonder that Mr. Louis Tossey, a member of the Detroit Common Council, took occasion recently to question the correctness of a quotation made from the report. The quotation was all right, but he had been led to believe all manner of roseate things. In the Lighting Board itself, Commissioner Ritter called the report "trash," but as he defended at the same time an official who was shown to be away on an excursion at the very time the books reported him on duty and "in charge," the Commissioner's views and expressions are entirely creditable to his feelings as a man and a politician. But there is a "difference" in the Board also over the report itself. It is a handsome document, with cuts on plate paper in colored inks, but it was rushed through with an eye to its effect on the League of American Municipalities, and was actually printed before the Board had even seen it, let alone approved it. The hind legs of the body kick; at least they do not work in unison with the front legs at such times.

If we want to see a really fine specimen of the way a good business man can do things when he becomes an official we have only to look at the superb administration of the War Department during the Cuban campaign. But the Detroit municipal plant does not pretend to live up to that high standard of efficiency—quite. Such as it is, however, it cannot be quoted as a spectacular achievement in the line of municipal managerial ability. It is in the same class, at long interval, with the electric lighting plant of Herington, Kansas, whose deficiency up to 1897 was \$5,200, and which is now being shut down on August 15 because it runs behind over \$150 a month. It is of the same breed at bottom as the natural gas plant of Toledo, O. That plant is now, we hear, in the market. It cost the city about \$1,750,000, for which bonds are outstanding at 4 per cent. In eight years the sinking fund has received \$10,000. The plant costs the city \$40,000 a year to operate or about twice as much as the revenue derived from the sale of gas. It hardly seems possible.

We are very tired of such municipal plant humbuggery and of the idea that the man in buttons can run things better than a private citizen as soon as he gets the buttons on. The last huge scandals in New York State canal administration would seem enough to warn against further attempts to administer commercial enterprises by public officials with public money. If the service is honest it costs above the market value. If the service is dishonest, there is no end to the leakage of funds which have to be met or raised by taxation. But we suppose the process of creating new departments for Tammanies to run will go on indefinitely, the delusion and deception being far too deeply seated to vanish because of any exposure.

Peace With Honor.

IN less than 120 days this country has carried out the purpose for which it went to war, and ends the conflict with Spain in a creditable, glorious manner, its armies and fleets victorious in both hemispheres. Spain is banished from the New World, and her colonies that have suffered so much and so long pass under our flag or under our protection. The evil that Spain did will long live after her, but at least a new start has been made. So, too, in the Far East. Just what will be the conclusion there it is hard to predict, but one thing is certain—the flag will not come down where it has been hauled up. No man, no party in power, will dare propose such a thing, and the peace of the world itself demands that where we have intervened there we shall stay to govern or to shield.

Bound up with all the new policies of the present and the future are vital questions of trade. We are a commercial people, a trading and a manufacturing nation, and the point has been reached at which larger markets are welcome and necessary. From Cuba and Porto Rico and the Philippines we were shut out by discriminating tariffs. Those tariffs will no longer apply. It is very unlikely, moreover, that this country will sit still now and see itself shut out of markets to which it has had access. We have not seen the old wall of China built up from the inside, crumble away, in order to rest supinely while to our hurt another wall is built around the Celestial Empire, from the outside, to exclude us. If we have to stand by England to keep the doors open we shall do it. If England falls down we shall

do it for ourselves. The ruler or country persistently antagonizing the United States is laying up a terrible retribution.

There are important days coming in the near future, in which America will play no mean part. Europe is shrinking visibly as compared with this United States and the other new nationalities growing up outside the Old World. The Atlantic is to-day not less, but the Pacific is more, and with the Nicaragua Canal cut our country will dominate both oceans irresistibly. Our responsibilities will be great, but it was never yet the disposition of the races underlying the Yankee breed to shrink from responsibility.

Out of the changed conditions will come a larger trade, and in the export of our products such articles as machinery, steel and iron and electrical apparatus will furnish a large proportion. Providence has favored us with skill to invent and build, and with illimitable stores of raw material, as well as with vast areas for the cheap growth of food. It would be strange indeed if we could not manufacture in the long run and at no distant date on a scale to transcend precedent and to defy competition.

Americans are not boasting in these days, and the above remarks are not intended to wear any aspect of self-glorification. On the contrary, the war has sobered us all, as the Civil War did, but it leaves behind it, as did that struggle also, a sense of national responsibility that must be and will be lived up to; a determination to be worthy of high destiny, and a conviction of ability to achieve and accomplish that cannot condone shortcoming of any kind in those who would lead among us. The country has no use for "small Americans" in large places.

The Present Status of the Calcium Carbide Industry in Europe.

WITH a big boom and many an unpleasant "bang," the new illuminant and so-called commercial revolutionizer, acetylene, was ushered into the field of practical technics a few years ago, in the expectation that it would furnish the ideal light, and work wonders in agriculture, medicine, and other fields. That it has not, as yet, done all these things, need not be pressed, but it certainly has done one thing which should be written to its credit, namely, it has given new employment to the electric current, and that on a very large scale, in the production of its parent, "calcium carbide." This has been brought about chiefly by the very extensive and highly commendable use of the new gas for the enrichment of illuminating gas used at present, and its employment for this purpose is steadily on the increase.

The commercial production of calcium carbide is of somewhat recent origin, in fact, only since the electric furnace was employed for smelting the lime and carbon. The German chemist, Wöhler, produced it in 1861; Berthelot, by another method, in 1866; Thos. L. Willson claims to have accidentally discovered the substance in 1888, and Moissan, the celebrated French scientist, read a paper on the production of it in an electric furnace, in 1892. Dr. L. K. Boehm, of New York, however, claims priority to all others in the production of the material by employing the electric current by referring to his patent filed Nov. 5, 1891, and granted on Dec. 24, 1895, a few months after the patent was granted to Mr. Willson, whose application was only made in January, 1895. This question of priority, however, interesting as it is, we will not discuss at present. What interests us to-day is the enormous production of calcium carbide in this country, cheapened by the power from Niagara, and the reports on the present status of carbide works in Europe.

Principal among the European carbide producing countries should be mentioned Germany, where, according to Consul General Mason, the demand has far exceeded the supply. This has necessitated the importation of large amounts of carbide from America and from Neuhausen, Switzerland, where enormous water powers are available for the running of electrical plants. It appears as if the whole carbide industry, so far as central Europe is concerned, is now in a transition stage and that the conditions of supply and price are likely to be greatly modified by the increased production of the coming year. One of the most important factors in this connection is the great combination headed by the Schuckert Electrical Manufacturing Company, at Nuremberg, which it is stated on good authority will increase its capital to \$7,000,000. They expect to have in operation during the course of next year, carbide factories at

Gampel, Sarpsborg (Norway), Bosnia and Brega (Catalonia), with a total of 18,000 horse power and an estimated annual output of 20,000 metric tons, capable of generating 211,896,000 cubic feet of acetylene. Besides these, the Aluminum Industry Co., of Neuhausen, is constructing a 7,500 h. p. plant at Land-Gastein, Austria. In all these establishments, the electric current will be used for the smelting together of the carbon and lime. A Leipzig company, with works at Cassel, are using the heat of darting acetylene flames for the smelting process, but it is questionable whether this new process can be made to compete economically with electrical heat generated by water power under favorable conditions; such as in use at Verrier, near Geneva, where the manufacture is carried on by means of the wasted water power of the Geneva electric light station. The use of acetylene for smelting the carbide seems somewhat of a reversible process, similar to running a dynamo by a motor which receives its current from that dynamo—a rather uneconomical method.

Another important fact which might be mentioned here is that calcium carbide is a somewhat critical kind of merchandise for international traffic, on account of the requirements of railways and steamship companies in respect to packing. These are so costly and difficult of fulfilment, that recently a large order of carbide for China had to be canceled because it was impossible to comply with the specifications for its transportation. Hence the desirability of local production.

The production of the substance in this country is in a most healthful condition, as may be judged from the following figures: The entire production of carbide in this country in 1896 is stated to have been 860 tons, and in 1897 it rose to 1,925 tons, while the Willson Company are stated to have produced 3,000 tons of carbide since January 1 of this year.

With these figures before us and the increased demand for acetylene for gas-enriching purposes, it would be rather difficult to set bounds to the future of the calcium carbide industry.

Trolleys on the Brooklyn Bridge.

THE cities of Brooklyn and New York have recently been greatly agitated by the report that the running of the trolley cars over the Bridge has injured some parts of the structure and made travel dangerous. We are glad to note that all who can speak on the subject with any authority assure the public that the danger, if it really exists at all, does not affect the Bridge proper but only minor, supplementary parts of the structure. The Bridge is held up by its cables and not by the framework under the roadways, where the "buckling" of the chords came, due to the heavy strain thrown on the "overflow stays." It is said that with a few remedial changes the structure has been put and will be kept in as strong and sound a condition as it ever was.

This is the second scare that has been raised over the use of electricity on the Bridge, and neither has been fully sustained, although both may have served a useful purpose in stimulating that vigilance requisite to the proper maintenance of every great engineering work. It was alleged that by the introduction of electricity on the Bridge a bad condition of electrolysis had been set up in the cables. Considering that the cables are anchored in huge masses of stone and concrete, that would seem improbable, but if it were possible we believe a sharp eye will now be kept open and all precautions put in force.

The Bridge as it stands to-day is in all probability a safe and sound structure, and to preserve it in such condition compels those in whose hands its life is entrusted to take care that no undue strains are placed upon it. This is no time to scoff at danger, but to devise means to remedy the necessary evils of transporting with safety large throngs of people in a short time during certain periods of the day. One cure, and one which should be applied at once, is the enforcing of the rule compelling the motormen to keep a headway of 102 feet between cars. This distance can be easily judged by the men themselves, if they remember that the trolley poles on the bridge are placed 50 feet apart. In the second place, the bridge should be, and doubtless is, carefully inspected at frequent intervals and constantly kept in good condition. The final remedy lies in subdivision of the traffic, or in other words, in the speedy completion of the new East River bridge. In this and in the construction of yet other bridges we may place our hopes as to the safety of the present imposing structure and the extension of electric roads.

NEWS & NOTES

The First Regiment U. S. Volunteer Engineer Corps.

THE departure from New York harbor last Wednesday, August 10, for the front in Porto Rico, of the First Regiment of the U. S. Volunteer Engineer Corps makes this a fitting occasion to review briefly the work that has been done in the last three months in getting this fine body of men together and in dispatching them, well trained and well equipped, to the scene of active operations. It is true that at this moment, when Spain seems to have got all she wants, there is a brighter prospect of peace than when the regiment sailed; but it will be strange indeed if engineers cannot find plenty to do in the West Indies that will inure more to the benefit of the beautiful islands henceforth under our care than "potting" a few miserable Spaniards.

GOING INTO QUARTERS AT CAMP TOWNSEND.

If there is any part of the world that needs engineering, it is the Spanish West Indies.

For electrical engineers, this Volunteer Engineer Corps has had a deep interest from the start. One of the prime movers in its organization was Capt. (now Colonel) Eugene Griffin, U. S. A., vice-president of the General Electric Co., himself an engineer of national reputation, and a man whose work when in the Engineer Corps at Washington is well remembered there. Besides this, the regiment as a whole, officers and privates, has been largely recruited from electrical ranks and from allied lines of engineering, so that in a way there is a distinct electrical tinge to the whole body. A great deal of the preliminary recruiting was done through Capt. Griffin's office in the Edison Building, until the scene shifted to the Army Building on Whitehall street, and then to Camp Townsend, at Peekskill, on the Hudson. As a matter of fact, the growth of the regiment was rather slow, from the very abundance of the material offered; and the scrutiny exercised was rigorous enough to satisfy the most exacting and critical. It is to be noted also that the regiment has been made up on a very eclectic basis. It has an enormous percentage of college bred men not only on the staff but in the rank and file. Almost every commissioned officer is

highly educated men permeating the regiment and many of them coming straight from their professional engineering careers are carpenters, riggers, linemen, dynamo tenders, bridge builders, boatmen, miners, locomotive and stationary engineers, etc., a wonderful aggregation of men who have been trained to do thoroughly something that fully justifies their selection and makes the regiment perhaps the finest body for technical skill ever got together in this country for a specific purpose of this kind.

About the last week in June, the regiment began to assemble

THE VOLUNTEER ENGINEERS AT CAMP TOWNSEND.

bit by bit at Camp Townsend, and Col. Griffin, now having been commissioned, took the men in hand, with his officers, to lick them into military shape. Necessarily a good deal of time was put into regular infantry drill, but it was engineering work the men all wanted to get at, and they probably had their fill before they struck their tents and came down the river to embark. An observer of the scene of departure, on August 4 and 5, says: "We cannot too highly praise Col. Griffin for executive ability

THE COLONEL.

THE HIGH PRIVATE.

displayed in the orderly departure of his regiment from Camp Townsend. Nothing was forgotten—everything connected. The transports were in readiness at 3 o'clock, and lay at a dock two and a half miles from the camp. At an early hour each officer's effects were packed and ticketed. The men waited, quietly and orderly, each and all equipped, even to a package of bread and meat for the sail down the Hudson. No confusion, no hurry, no noise. Capt. Shaler, an officer of ability and precision, was detailed to see that the camp was left in perfect order. Not a

FIRST REGIMENT, U. S. VOLUNTEER ENGINEER CORPS, ON PARADE, CAMP TOWNSEND, PEEKSKILL, N. Y.

a graduate of a university or technical college, Cornell, West Point and Harvard being well in the lead, with Yale in second place, and Columbia, Johns Hopkins and the Massachusetts Institute of Technology in the third place. Taking the regiment as a whole, Cornell is said to be most largely represented, with the University of Pennsylvania perhaps second. With such

bit of paper or crust of bread marred the outlook; not a man ill, save those who had been stunned by the lightning storm of Thursday. A splendid-looking lot of men these 1,200 engineers—steady, law-abiding, intelligent. And so, on the calmest and most beautiful of evenings, they floated down the Hudson River and found the City of Chester in the harbor, near Bedlow's Isl-

and, awaiting them. There has been so much said about the confusion and misery incident to the embarking of our troops that I feel it my duty and pleasure as an eyewitness to give to

a beautiful Colt rapid-fire gun, which the men received very enthusiastically. In fact, the gallant Volunteer Engineers were made to feel and know in many ways that their brethren staying

COL. EUGENE GRIFFIN AND OFFICERS, FIRST REGIMENT, U. S. VOLUNTEER ENGINEER CORPS.

Col. Griffin has justly earned praise. Surely that was a master mind that organized the leave-taking of the First New York Volunteer Engineers."

Arrived in the harbor, the men found the City of Chester awaiting them, but had three or four days of uncertainty and delay, while the steamer was being got fully ready and loaded for her voyage. The regiment occupied a good position of

behind took the deepest concern in their welfare and would follow their fortunes with warmest interest.

There were, of course, many indications of the calibre of the men, individually and collectively, before they left, but perhaps the best is the tribute said to have been paid them, unconsciously and in a plain, matter-of-fact way by the quartermaster, who is understood to have reported unusual difficulties in the equipment of the whole regiment with uniforms. "The trouble is," he said, in a moment of perplexity, "I have clean run out of large sized hats and small sized shoes." This is one of the stories so good and neat that if not true it deserves to be. We do not know that the Engineers would ask any higher compliment, except to be known as brave; but that glory the whole army shares with them.

Our pictures speak for themselves. For the photographs of

"CITY OF CHESTER" WITH TRANSPORTS, N. Y. BAY.

vantage in the middle of the harbor, and spent no small part of its time exchanging cheers with pleasure and business craft, until at last it was humorously proposed to have a regular detail to attend to that patriotic function. Before it left, the regiment was presented by the Engineers' Club of New York

WHEN THE WATERMELONS CHEERING THE SANDY HOOK BOAT. CAME ALONGSIDE.

with a stand of colors, which was highly appreciated. President Thomson, of the club, was active with other members in raising a subscription to present the regiment with a portable field electric searchlight, and he also secured for it from the Colt Armory

WATCHING THE EMBARKATION IN N. Y. BAY.

Ed. Elec. Engineer.

John Thomson, Pres. Engrs' Club.

the staff and the regiment on parade, we are indebted to Manser, the Peekskill photographer. The smaller views are from snap shots secured by Mr. W. J. Clark, railway department manager, General Electric Company, who both at camp and on the City of Chester took a great many characteristic bits. It will be seen that the men went at their work and play very heartily, making a good record in camp and adapting themselves with cheery good humor to the unwonted cramping conditions of a troopship. During the stay in the harbor, under the blaze of an August sun, lying at anchor, life was not altogether a grand sweet song, and the boys were delighted when Col. Griffin secured for them two pleasant barges and moored them alongside, so that they could stretch their legs in the daytime and find hard, cool planks at night. But all these discomforts were forgotten at last in the delight of sailing away to encounter others of a worse description, as well as possible loss of life or limb, for the glory of the Stars and Stripes.

Extension of Electric Traffic at the New York and Brooklyn Bridge Terminus.

On Monday week, the new motor cars with which the Brooklyn Elevated Railroad Co. has been experimenting began their regular trips across the bridge. They are used to draw the elevated trains from Bridge street across the bridge and back again, making a continuous trip. They have been working very successfully and the officers are so well pleased with the tests that it is only a matter of time before the system will be extended to all the branches of the line.

It is expected that the new arrangement will permit the running of trains under four-minute headway instead of eight minutes headway as at present. Furthermore, it will not be necessary to make any change of cars, as is now the case, in rush hours.

Since the trains of the Brooklyn Elevated system began running over the bridge a month ago, they have been taken by the ordinary locomotives to the bridge yard, where they were attached to one of the bridge motor cars, and thence drawn out of the station to the cable.

Chief Engineer Cornell, of the company, states that the next move the company would take would be to introduce the third-rail system on the Fifth avenue line. This line is the shortest and most remunerative in the system, and if it works successfully will then be extended to the Myrtle avenue, Lexington avenue and Broadway lines.

Electrical Activity in Chicago and Vicinity.

MONTGOMERY WARD & CO., the great mail order retail house of Chicago, will put in a large electric plant for the new building it is erecting. For this purpose two vertical, cross compound 300-horse-power Allis-Corliss engines have been contracted for. To each engine two 100-kilowatt dynamos will be direct connected. The generators are 110-volt and are to be supplied by the Western Electric Company from its Chicago factory. The Allis vertical engines will run at 125 revolutions per minute and are to be equipped with a new style of valve, which is located in the cylinder heads, so as to reduce the necessity for clearance between piston and cylinder head at the end of a stroke to the smallest possible amount, thereby securing an increase in economy. This location of the valves in the cylinder head is a novelty in modern Corliss engine construction and one for which the builders are able to make some low guarantees as to water consumption. The new building this plant is to supply will be wired for 8,000 incandescent lights. Steam is to be supplied by three Heine water tube boilers rated at 250 h. p. each, 150 pounds steam pressure. With them the Hawley down draft furnace will be used. The engine room is to be fitted up for beauty as well as utility and will be finished in marble with glass partitions. The estimated total cost of this electrical plant is \$40,000. Fourteen electric elevators are contemplated. One of the features of the new building is to be a tower 362 feet high, which will be the highest structure in Chicago.

A. H. Andrews & Co. are to put in a 200 h. p. plant for power transmission at their wood-working factory at Twenty-second and Fiske streets, Chicago.

Nelson Morris & Co. will change their plant at the Chicago stock yards from mechanical to electrical transmission, and for that purpose will put in 400 kilowatts in generator capacity and 650 horse power in motors. The same concern has just installed in its plant at East St. Louis, Ill., a direct current plant with 125 h. p. in motors.

The J. Gund Brewing Company in the last six months has put in for use around its brewery a 75 kilowatt three phase generator and 150 h. p. aggregate capacity in three phase induction motors, on a 220-volt system. An addition to this installation is now being made in the shape of 100 h. p. more in generators and motors.

The United States Sugar Refinery at Waukegan, Ill., has just contracted for two 180 kilowatt two phase 440-volt generators and 600 horse power in type C Westinghouse induction motors for shop lighting and transmission.

The Schoenhofen-Edelweisse restaurant at 103 Madison street, Chicago, is starting a 60 kilowatt double commutator dynamo for lighting and power purposes. This double commutator machine was built by the Western Electric Company and

has proved very popular around Chicago. Each commutator gives 110 volts, so that 110 and 220-volt circuits can be run from the same machine, or if desired, an Edison three-wire system can be run from the one machine. This dynamo is run by a 12x12 Ball engine, to which it is direct connected. The speed is 325 revolutions per minute.

These plants are some of those looked after by one consulting engineer, F. D. Mack, and are only a few out of the many new projects under way in this territory. No wonder electrical manufacturers are kept busy these days.

FRESNO, CAL. Shortness of the water supply in the mountains forced the San Joaquin Electric Co. to shut down part of its plant for a time.

Boiler Test Meters—Worthington Steam Accumulator.

AT the regular meeting held August 9, of the Civil Engineers' Club, of Cleveland, Dr. Lehman B. Hoit read a paper on "Test Meters for Boiler Plants." After describing the requisites of a water meter, as attached to a service pipe to measure the total consumption, he emphasized the importance of perfection of parts and accuracy of record in the meter applied to determine the amount of water fed to steam boilers. The old method of testing boilers by weighing the water cannot be applied for general use owing to the fact that the expense of so doing would in the end amount to more than the saving effected by the observations made. It is a common experience that in every-day service the fuel consumption is much greater than that determined by the test trial. An accurate meter serves the purpose of a daily and continuous test and is as essential in determining the efficiency of boilers and the relative value of fuels as the steam indicator is in determining the power developed by the engine. By noting the readings on the log book in charge of the engineers, the duty performed by the boilers is recognized. Incidentally the test meter also indicates the relative skill of different sets of firemen and tends to prevent waste on their part. The speaker then exhibited and described a Worthington meter, and cited instances of its successful application to large boiler plants. The error in measurement in these modern machines has been proved to be only a small fraction of 1 per cent., and the rate of error being constant may easily be eliminated in the general result. The paper was discussed by Messrs. Palmer, Roberts, Porter and others.

By request, Dr. Hoit exhibited some blue prints of the Worthington steam accumulator, and described its construction and operation. As compared with a weighted accumulator, this has several advantages. It requires no bulky weight, no heavy foundations, and produces no water hammer requiring extra strength in connections. The water hammer of a weighted accumulator often amounts to 25 per cent. and sometimes 50 per cent. of the static pressure. It is particularly adapted to the regulation of plants operated by water pressure, such as hydraulic presses and passenger elevators. A sudden demand in the service by reducing the water head causes additional steam to be supplied to the pumps, and also in certain cases to an auxiliary pump, by which means the loss of head is promptly restored. The whole action is automatic and requires no attention on the part of the engineer. In large plants, and especially where the service is very fluctuating, these machines have proved very advantageous and economical. The effect of the accumulator is somewhat analogous to that of a steam governor. This subject was discussed by Messrs. Herman and Palmer, and Dr. Hoit kindly answered a number of questions.

OTTO GAS ENGINES. Up to the end of 1897 no fewer than 61,370 of these engines had been sold, of a total of 508,025 brake horse power. This does not include Otto oil engines, of which many have been sold. Of these engines, 16,193 were sold in Germany, 30,973 in Great Britain and 14,204 in other countries.

Use of Alternate-Current Motors in a Bleaching and Dyeing Establishment Providence, R. I.

THE old-time prejudice against the alternate-current motor has become nothing more than history, and it is interesting to note that this type of machine has demonstrated its superior utility to the direct current motor in a number of peculiarly trying applications.

As the original promoters of the use of alternating apparatus, the Westinghouse company have been pre-eminent in the development of machinery of this type, whether in monophase or polyphase systems. The culmination of such developments to the present date is no doubt to be witnessed in the Tesla "Type C" induction motor, as made by that firm. This motor has been frequently described in these columns, and the essential feature—the absence of any connections between the mains and the rotating parts—is familiar to every electrical engineer. The installation of these motors by the Silver Springs Bleaching and Dyeing Company, of Providence, R. I., has shown their fitness for a peculiar line of service in which the use of direct current motors would be impossible.

This company, under the ownership of Governor Lippitt, of Rhode Island, was a pioneer in the use of electrical apparatus

installed. These motors are employed for driving washing machines, ironing machines, tentering frames, triplex pumps, elevators, ventilating fans, etc., etc. Some of the motors operate constantly in a cloud of steam where a direct current motor could not run for five minutes. Many of them are subjected constantly to the action of chloride fumes, and all the copper parts of the motors and switches are green with corrosion. In many of the operations enormous starting torque is required, the initial torque in some cases being four times the normal torque of the motor.

The plant has proven so satisfactory that it has recently been extended by an installation of ten more of the Tesla "Type C" motors made by the Westinghouse Company.

Commercial Development of Electro-Chemistry in England.

MR. JAMES BOYLE, United Consul at Liverpool, England, writing on the British chemical trade, says:

The electrolytical method for the manufacture of chloride of potash, bleaching powder, and caustic soda for the decomposition of salt, instead of the employment of bi-sulphuric acid, has been in use for some time in Germany, and also to a small ex-

WESTINGHOUSE INDUCTION MOTOR ATTACHED TO A TRIPLEX PUMP.

for mill purposes. Very early in the history of the use of electrical industry Governor Lippitt purchased two direct current dynamos, which were used for lighting and power service until 1895. At this time the necessity for large extensions of the Silver Springs plant induced the company to investigate the modern developments in lighting and power service. After a thorough study of the subject and visits to all the electrical factories Mr. E. C. Myrick, the company's engineer, recommended the adoption of the Westinghouse three-phase system, 3,000 alternations, for both lighting and power.

This decision was at the time severely criticised by several mill engineers, but the results of two years of active service under the worst imaginable conditions have fully demonstrated the soundness of engineering judgment manifested.

In addition to lighting the entire plant, some 30 Westinghouse induction motors of from 3 to 75 horse-power have been

tent in the United States. It is claimed, that by the application of electricity, the chemicals can be produced more cheaply than by the old method. The electrolytical methods do certainly produce more direct results, but local experts say that it is yet too soon to definitely decide whether they are more economical than the old method, as there are so many considerations which time alone can solve, such as the wear and tear of machinery and the cost of replacement, which are expected to be serious items of expenditure. Where electricity can be produced by water power, as in Norway and at Niagara and other places in the United States, the new process will have a better chance of success than in England, where it must be produced at great cost in the consumption of coal. The various electrolytical processes in use in this neighborhood are:

(1) Richardson & Holland's patents, which are being worked at Parr (St. Helen's), but apparently so far are not proving a

commercial success, although over \$486,000 have been employed in perfecting them.

(2) Castner-Kellner's patents, worked at Weston Point (Run-corn). The company holds out the promise of being able to make a return of 8 per cent. per annum to their shareholders next year. For the last year they were paid nothing.

(3) Hargreaves & Bird's patents, works for which are being erected at Middlewich in Cheshire.

(4) The Rhondin process, for which a prospectus was issued inviting the subscription of capital. This was not allowed to go further, as the Castner-Kellner Company obtained an injunction restraining the Rhondin Company on the ground that their process was an infringement of the Castner-Kellner patents.

Speaking generally, there has been a steady decline in prices at Liverpool, dating from 1893. The following figures show the downward movement:

Sulphate of Ammonia.—In 1893, \$68.13 per ton; in 1897, \$40.14.

Caustic Soda.—In 1893, \$46.22 per ton; in 1897, \$35.88.

Soda Ash (Leblanc).—In 1893, \$22.50 per ton; in 1897, \$21.89.

Chlorate of Potash.—In 1893, 16 cents per pound; in 1897, 7.6 cents.

Bleaching Powder.—In 1893, \$41.36 per ton; in 1897, \$30.40.

Muriate of Ammonia.—In 1893, \$4.86 per cwt.; in 1897, \$4.25.

Carbonate of Soda.—Prices have slightly fluctuated; in 1893 the price was \$19.46 per ton; in 1897, \$20.67.

Sal Ammoniac.—The price has been very steady from 1893 to 1897, it being about \$8.51 per cwt. for first quality and \$8.02 for second quality.

M. HENRI MOISSAN has succeeded in obtaining metallic calcium free from impurities. He dissolves the crude metal in molten metallic sodium, maintained at a red heat. On cooling the calcium crystallizes and is separated by being treated with absolute alcohol. The crystals are white and shining and belong to the hexagonal system.

Fire and Police Superintendents in Convention

THE International Fire and Police Telegraph Superintendents' Association held an interesting and successful convention at Elmira last week, when a number of papers were read by members and experts—Capt. W. Brophy, on "Electrolysis and the Best Means of Prevention;" Morris M. Mead, on "Maintenance of Central Office, Embracing the Storage Battery;" W. H. Thompson, on "Aerial Construction;" F. P. Foster, on "The Difficulties of a Superintendent;" J. W. Aydon, on the work of the Association.

Special honors were paid to Dr. Channing, one of the fathers of fire alarm telegraphy, who sent a communication to the meeting and to whom a message of congratulation was returned.

Mr. Clarence E. Stump, the well known publisher of "City Government," made a very happy and suggestive reply to the mayor's address of welcome.

The treasurer's report showed a balance of \$240.

A change was voted in the constitution, making dues \$10 instead of \$5.

J. W. Aydon, of Wilmington, Del., was chosen president, and Wilmington selected as the place for the meeting in 1899. The other officers elected are: Vice-president, George F. Macdonald, Ottawa, Canada; treasurer, Adam Bosch, Newark, N. J.; secretary, H. F. Blackwell, Jr., New York; financial secretary, Bert McAllister, Bradford, Pa.

A number of entertainments marked the occasion and good fellowship prevailed. Those in attendance were: Frank C. Mason, Brooklyn, superintendent police telegraph; William B. Green, Brooklyn, Brooklyn Daily "Eagle;" A. P. Eckert, New York City, Safety Insulating Wire and Cable Company; Frank P. Foster, Corning, superintendent fire telegraph; John B. Taltavall, New York, the "Telegraph Age;" Burt McAllish, Bradford, Pa., superintendent fire telegraph; H. H. Blackwell, Jr., New York City, superintendent fire alarm; Thomas J. Welsh, Buffalo, superintendent fire telegraph; George F. Porter, New York, Kerite wires and cables; W. S. Eckert, New York, John

A. Roebling's Sons' Co.; Clarence E. Stump, Brooklyn, "City Government," New York; William A. Baines, Bridgeport, Conn., superintendent fire telegraph; Louis W. Miller, Rochester, superintendent police and fire telegraph; Morris W. Mead, Pittsburgh, superintendent Bureau of Electricity; H. C. Bundy, Watertown; superintendent fire alarm; William Brophy, Boston, Mass., inspector of wires; Frederick Pearce, New York, Lema Lemon and wife, Baltimore, superintendent fire telegraph; Adam Bosch, wife and daughter, Newark, N. J., superintendent fire alarm system; Frank M. Perrin, Boston, Mass.; W. H. Thompson, Richmond, Va., superintendent Fire Telegraph Company; George T. Manson, New York, Okonite Company; J. W. Ogden, wife and daughter, T. J. Harper, Atlanta, Ga., city electrician; William Exall, Newark, N. J., captain hook and ladder company, Newark Fire Department; George F. Macdonald, Ottawa; superintendent fire alarm; William Crane, Erie, Pa., city electrician; S. L. Wheeler, Springfield, Mass., city electrician; A. C. Mackenzie, Elmira College; E. J. Fenlon, National Conduit Company, New York; G. L. Wiley, New York; W. Y. Ellett, Elmira.

The American Street Railway Association.

We are requested to publish the subjoined:

I desire to remind all our members that the next meeting of this association will be held at Mechanics' Association Hall, Huntington avenue, Boston, Mass., September 6, 7, 8 and 9, 1898. We expect to have the largest convention we have ever held. Papers will be read on live subjects. The exhibits will be a prominent feature of the meeting. Full particulars in regard to hotels, railroad rates, etc., were given you in circular of May 1. In order to secure reduced fare you must get a certificate from the agent when you purchase your railroad ticket. Headquarters at Hotel Brunswick. Please fill out and mail at your earliest convenience the enclosed card. Hoping to have your company represented, I remain, Yours very truly,

T. C. PENINGTON, Secretary and Treasurer.

Chicago, August 1.

The Coming Mechanics' Fair in Boston.

The spirit of progress which has characterized the executive committee having in charge the twentieth triennial exhibition of the time-honored Massachusetts Charitable Mechanic Association in Boston is again strikingly apparent in several important directions. Not only have the character and scope of the exhibits themselves been elevated and broadened, but the building, with its immense floor area and exhibition resources, has been remodelled and greatly improved.

Latest reports from the several departments point to the most interesting exhibition in the history of the association, and presenting to the world for the first time in history a great fair entirely driven by electricity as a motive power.

Applications for space continue to pour in, and the managers find themselves confronted by the necessity of selecting only those of the greatest public interest. This means that intending exhibitors should lose no time in inspecting the floor plans and filing early applications if they hope to be represented in the Mechanics' Fair of 1898, which opens October 10.

Further Trade Improvement.

The general conditions of the country at the opening of the Fall trade are certainly better in every direction, and the reports as they come in go to show that present tendencies toward improvement will become more marked now that peace is declared.

During the past week the stock market has been strong and very active. Of Western Union 30,163 shares were sold around 94¼. General Electric closed at 41, after sales for the week of 19,605 shares. In Boston, American Bell Telephone went to 280½. New York Edison sold at 132¾.

Copper New York is quoted at 11.75 cents. Heavy steel rail, Eastern mill, is \$18 per ton. There is considerable hardening in the quotations for iron and steel.

McGill University—The W. C. McDonald Chair of Electrical Engineering.

The Board of Governors of McGill University, says the Montreal "Witness," have appointed Prof. R. B. Owens, E. E., of the University of the State of Nebraska, to the W. C. McDonald chair of electrical engineering at McGill University, lately held by Prof. Carus-Wilson. Prof. Owens is a native of Maryland and was educated at the Johns Hopkins University in Baltimore, obtaining a high standing in mathematics and physics. Proceeding from the Johns Hopkins University to Columbia University, he there obtained in 1891 the post-graduate degree of E. E., being a member of the first class in the United States to obtain this degree. In the intervals of his college course the young student acquired a fund of practical knowledge with several well-known electrical companies. Shortly after receiving his degree Mr. Owens was appointed adjunct professor of electrical engineering in the University of Nebraska, and in 1894 he was made full professor, having in the meantime served as one of the judges of electrical exhibits at the World's Fair. Prof. Owens has recently been elected to a Tyndall Fellowship by Columbia University and is Director of Bureaux of Electricity and Machinery at the Trans-Mississippi Exposition at Omaha. He is also a member of the Western Society of Engineers, the American Society of Mechanical Engineers and the Council of the Society for the Promotion of Engineering Education, and vice-president of the American Institute of Electrical Engineers. He has contributed important articles to engineering societies and to the electrical press on the subject of electro-technics and of technical education. Since his entrance into the educational field Professor Owens' work has been marked by originality and energy. He has built up the course at the University of Nebraska to a prominent place in the rank of technical institutions, and his activities, not being limited to the precincts of the college, having taken him into outside matters of national importance. He will, no doubt, add to his reputation at McGill.

MR. SEATON M. SCOTT, consulting engineer, 123 Liberty street, New York City, has just completed a set of plans for an electrical 'bus seating eighteen persons inside and four persons on top for the Electrical Vehicle Co., of this city.

MR. MARTIN J. INSULL, who has recently opened headquarters in the Monadnock Building, Chicago, as a manufacturers' agent, was in New York last week.

MR. E. L. BRAYTON, treasurer of the Pelton Water Wheel Company, San Francisco, who has been at their office in New York City for some weeks past, has gone abroad in the interests of his company.

Dr. G. Q. Colton.

We note the death at the ripe age of 84 of Dr. G. Q. Colton, a famous American dentist who fifty-four years ago was closely associated with Dr. Horace Wells in some of the early work in the use of anaesthetics which led afterwards to a fierce controversy as to priority amongst several men. Some fifty years ago he went over the country lecturing on popular science, and having with him a small model railroad built by Dr. Lilley, one feature of which was the use of the track as the return cir-

cuit. A few years ago one of the editors of The Electrical Engineer traced the history of the occurrence, and at last the old model was itself found, being put on view at the New York Electrical Exhibition of 1896. Dr. Colton was interested in science to the last, and so active that he went to Europe three months ago for change. His death took place at Rotterdam. It is said he extracted one million teeth, nearly all with the aid of nitrous oxide gas, and without an accident.

J. J. Schoenleber.

Mr. John J. Schoenleber, proprietor of the Northwestern Engineering Co.'s electrical supply office, St. Paul, died on August 4 after an illness of only two days. A year ago Mr. Schoenleber underwent an operation for appendicitis, from the shock of which he never fully recovered. He was a young man of estimable character and a graduate of Iowa State College. After finishing at Iowa he went to Purdue University and completed a special course in electrical engineering. He went to St. Paul in 1893 and engaged immediately in the telephone and electric supply business. Arrangements had just been completed for organizing a stock company under his supervision. Mr. Schoenleber was born at Ransom, Ill., in July, 1866. He had taken out several patents chiefly in the telephone field.

MR. GEORGE B. RICHMOND, of Lansing, Mich., has just died, and is credited with having invented the telephone. Sorry to say we do not know the gentleman.

QUANTITATIVE CHEMICAL ANALYSIS BY ELECTROLYSIS. By Dr. A. Classen, in co-operation with Dr. W. Löb, translated by W. H. Herrick, A. M., and Bertram B. Boltwood, Ph. D. John Wiley & Sons, New York, 1898. 301 pages; price, \$3.00.

For a long time past there has been a demand for a reliable American treatise or translation of a work on chemical analysis in which the electric current is employed. It appears as if this demand has been admirably met by the translation of the above mentioned work, which has just made its appearance. Such a work will certainly find a ready market since the investigations of recent years have largely enriched this subject. The book contains specific directions concerning electrode tension, current strength and decomposition tension. The values given by the author have all been determined experimentally by himself and methods employed by other authors are omitted when they contain uncertain and impracticable data. The book has been made more complete by the description of various electrical instruments together with an explanation of simple and complete appliances for carrying out electrolytic experiments. The quantitative determination of a large number of metals, as well as their separation when combined, is given, and numerous applied examples of electro-chemical analysis are included. The book is profusely illustrated and well indexed, and the author has found it advisable to quote under each new metal treated all references bearing on that particular question. This must certainly prove of great value to anyone who wishes to make this subject a special study or is engaged in making electrolytic quantitative analyses.

Maver on Underground Work.

It is announced that Mr. William Maver, Jr., will shortly have in the publishers' hands a book on "Electrical Underground Conduits and Cables." Mr. Maver, it is well known, has been actively connected with electrical underground work since its inception in this country and has already written extensively on these subjects for current electrical periodicals, etc. His contributions on the subject to this journal will be well remembered. From Mr. Maver's well known attention to details in technico-literary matters it may be confidently predicted that this handbook will fill a want which at present exists in the literature of this branch of the art.

LETTERS TO THE EDITOR

Preventing Collisions at Sea.

WITH pleasure I note a comment by Mr. W. J. Clarke in your issue of Aug. 11, referring to my article "Means for Detecting the Presence of a Vessel or Iceberg." (E. E., Aug. 4.) In answer to Mr. Clarke's statement: "I am nevertheless of opinion that the use of wireless telegraphy apparatus is the only successful way in which collisions at sea can be avoided," I would repeat a statement already made in my original article, that in the employment of signalling apparatus we are dependent upon the watchfulness of the other vessels and also upon unavoidable circumstances which we cannot control. I should also like to ask Mr. Clarke in which way he would use wireless telegraphy to prevent a collision with icebergs. This apparatus needs an attendant, and it seems rather absurd to imagine a telegraph station on top of each iceberg.

The danger of collision with them prevails, and to substantiate this I quote a heading from the Newark "Evening News" of August 5, 1898: "Ocean Liner Probably Lost. Big Steamer Seen to Collide With an Iceberg and Go Down. Those on Board Unable to Escape."

The ideal method for preventing collisions at sea would certainly appear to be that which automatically indicates the approaching objects and would indicate their movements. Then we can evade danger. Even if two or more vessels would be approaching we would know exactly where they are and in which direction they are moving. With such an apparatus entire independence is established.

I understand, of course, that my device needs considerable experimenting before it can be called a practical means for the prevention of accidents at sea. However, in order to bring about a speedy settlement of the question of its practical value I repeat that discussion on it will be welcomed, and express the hope that the needed capital to carry on the investigations will soon be forthcoming. HERMANN HERBERTS.

Newark, N. J., August 12, 1898.

LEGAL NOTES

Suit to Stop General Electric Reorganization.

Suit has been commenced in the United States Circuit Court, Boston, by Thomas T. Livermore, Edwin F. Atkins and Quincy A. Shaw and the American Loan and Trust Company, all of Massachusetts, against the General Electric Company, of Schenectady. The suit is brought to restrain the defendant from decreasing the preferred stock of the company and allowing the complainants to receive their accumulated dividends.

The Value of A Child—A Trolley Accident Case.

In the New Jersey Supreme Court, in setting aside the verdict of \$5,000, obtained by Abraham L. Graham against the Consolidated Traction Company, for the killing of his child, Justice Gummere holds the damages to have been excessive, and he makes this declaration: "It is the universal rule that children are expensive, and not a pecuniary benefit to the father, and yet on the theory on which this verdict is based the larger a man's family the richer he will die. In the present case, if the father of the child had a reasonable expectation of being benefited in dollars and cents to the extent of \$5,000 by the continuance of the life of his child a family of ten sons would justify the assumption that at his death he would be \$50,000 better off than if he never had issue."

JUDGE BATES, of Bates & Holliday, 711 Tremont Building, Boston, has prepared an article on the new Bankruptcy Law, which will be sent to any one who may make a request for it, as long as the supply lasts.

REPORTS OF COMPANIES

Westinghouse Retirement of Floating and Bonded Debt.

It is officially announced that the directors of the Westinghouse Electric and Manufacturing Company have, by authorizing the issue of \$3,500,000 15-year 5 per cent. gold debenture certificates and by selling \$3,000,000 of such issue, completed a financial transaction of great advantage to the company and its stockholders. The company has been able to place these certificates without creating any mortgage upon its assets, the company simply covenanting that it will not hereafter create any lien upon its property. The proceeds of the sale of these debentures will retire the outstanding floating and bonded indebtedness of the company, returning to its treasury as available assets stocks and bonds in various lighting and power companies yielding an annual income exceeding one-half of the interest charges of the debenture certificates. The saving in interest to the company will be important but inconsequential as compared with the strong position the company will hereafter occupy with its rapidly increasing trade, to care for which the company will have ample resources. The interest coupons of the debenture certificates will be paid July 1 and January 1 by the Mercantile Trust Company, of New York, which acts as trustee under the agreement, the provisions of which have, under the advice of counsel in the interest of large investors, been made to carefully guard the interests of the certificate holders.

Pittsburg United Traction Co.

The United Traction Co., of Pittsburg, makes the following statement for the year ending June 30:

Gross earnings	\$1,475,764
Expenses	685,819

Net earnings	\$ 789,944
Fixed charges	590,445

Balance	\$ 199,499
---------------	------------

The preferred dividend calls for \$150,000, so that \$49,000 is left for the common stock, of which there is \$17,000,000.

GENERAL ELEC. CO. Over 95 per cent. of the stock was represented at the special meeting last week to scale down the capital stock 60 per cent., and owing to the work involved the vote was postponed until the 17th.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued August 2, 1898.

Alarms and Signals:—

ELECTRICAL SIGNALING APPARATUS FOR TRANSMITTING COMMANDS. C. Arldt, Berlin, Germany, 608,246. Filed Dec. 20, 1897. Details of construction.

BATTERY ZINC. D. Ogden, Columbus, Ind., 608,216. Filed April 12, 1897. A battery cell having a cover provided with an opening for the introduction of the electrodes, two or more electrodes with stems, and means for securing the stems within the opening whereby the electrodes may be suspended within the cell.

Batteries, Secondary:—

BATTERY ELECTRODE. H. E. Wilkinson, Mount Vernon, N. Y., 608,537. Filed June 10, 1897. A battery plate constructed of resilient spring metal and provided with a pocket having a front slide sloping inward toward its bottom, and ends which converge in a downward direction and are at angles to the sloping front side.

Conductors, Conduits and Insulators:—

FLEXIBLE METALLIC TUBE-CONDUIT. C. Husman, Osnabruck, Germany, 607,932. Filed Nov. 20, 1897. Composed of several separate tubes laid up together like the strands of a rope.

JOINT FOR ELECTRIC CONDUCTORS. H. S. Patten, Montclair, and W. Maver, Jr., Jersey City, N. J., 608,412. Filed Dec. 31, 1897. Comprises the conductors and their insulating coverings with coup-

lings to which the ends of the conductors are soldered, the couplings having lapping ends with closely fitting surfaces, and a clamping device for holding them together.

Distribution:—

ELECTRICAL DISTRIBUTION. C. P. Steinmetz, Schenectady, N. Y., 608,307. Filed July 14, 1894. Comprises means for obtaining polyphase currents by interlocking a number of sources of alternating electromotive forces in such a manner that a desired difference of phase is maintained between the different machines, which difference of phase is stable.

SYSTEM OF ELECTRICAL DISTRIBUTION. C. P. Steinmetz, Schenectady, N. Y., 608,308. Filed July 14, 1894. Similar to above.

Dynamos and Motors:—

ALTERNATING-CURRENT INDUCTION MOTOR. C. S. Bradley, Avon, N. Y., 608,249. Filed Oct. 22, 1895. Is provided with two independent field magnets wound to develop rotary magnetic fields, and two armatures of relatively high and low resistance co-operating with the fields.

ARMATURE FOR DYNAMO ELECTRIC MACHINES. E. H. Anderson and D. P. Thomson, Schenectady, N. Y., 608,277. Filed Jan. 8, 1898. Embodies a toothed armature-core, and openings in the core between the teeth and the main body of the core for limiting the cross-section of iron at that point.

COMMUTATOR. W. B. Potter, Schenectady, N. Y., 608,299. Filed April 27, 1898. Comprises a commutator segment, having a substantially straight side which forms the face side of the commutator when assembled, a lead slot, a groove into which the slot extends, and a securing lug.

Electro-Therapeutics:—

GALVANIC BATH. C. E. Schnee, Carlsbad, Austria-Hungary, 608,228. Filed Sept. 14, 1897. Means for directly introducing medicaments into the tissues of the human body by means of hand and foot baths or arm and knee baths.

Lamps and Apparatuses:—

ELECTRIC ARC LAMP. C. A. Pfluger, Chicago, Ill., 608,269. Filed Aug. 7, 1896. Comprises a fixed box with current controlling devices therein, tubes downwardly projecting therefrom and carrying each one conductor, and means associated with such fixed box and adapted to engage the carbon-rod tube of the lamp so as to hold it in position.

ELECTRIC HEADLIGHT LAMP. H. P. Wellman, Ashland, Ky., 608,497. Filed Dec. 10, 1897. Employs a parabolic reflector secured to the upright bar of the lamp frame, a translucent casing projecting through the reflector, supports therefor outside of the reflector, closures over the ends of the casing, and carbons secured to the inner ends of the rods.

Miscellaneous:—

IGNITER FOR GAS ENGINES. R. B. Hain, Grand Rapids, Mich., 607,992. Filed April 8, 1896. Details of construction.

RECIPROCATING ELECTRIC DRILL. H. Casler, Canastota, N. Y., 608,176. Filed March 18, 1898. Employs energizing coils having magnetic core within the same, a casing for the coils composed of an exterior shell, heads and an interior lining-tube all of iron or steel, and united by water-tight joints.

METHOD OF MANUFACTURING PRINTING BLOCKS IN COPPER, NICKEL, ETC. L. Boudreaux, Paris, France, 608,248. Filed July 15, 1896. Consists in applying a solvent to the surface of a plastic block, sprinkling its surface while in a soft state with metallic powder, removing superfluous powder when dry, and pressing the metallized block upon the etching to be reproduced.

SYSTEM FOR HEATING BY ELECTRICITY. J. F. McElroy, Albany, N. Y., 608,211. Filed Nov. 16, 1892. Consists of a plurality of heaters, each made up of a multiplicity of heater-sections, each of the heater sections arranged to be connected up in separate circuits, with means for varying the connections.

ELECTROLYTIC APPARATUS. J. G. A. Rhodin, Eccles, England, 608,300. Filed Aug. 11, 1897. Designed for the electrolysis of salts and employs an outer vessel of iron and an inner vessel of earthenware.

ELECTRO-MECHANICAL LOCK. H. G. Carleton, New York, 608,319. Filed Sept. 9, 1897. Details of construction.

ELECTRIC COMBINATION LOCK. H. G. Carleton, New York, 608,320. Filed April 4, 1898. Details of construction.

ELECTRIC LOCK. H. G. Carleton, New York, 608,321. Filed May 24, 1898. Details of construction.

AUTOMATIC SWITCH FOR REGULATING ELECTRIC AIR COMPRESSIONS. M. Moseley & Funck, Rochester, N. Y., 608,340. Filed Nov. 15, 1897. Combines an electric motor and compression pump with an automatic switch for controlling the motor-circuit, consisting of two communicating cylinders provided with pistons, suitable insulated contacts, one of which is movable, and operated by the movement of one piston produced by the admission of air to its cylinder by the movement of the other piston.

ELECTRIC HEATER. J. F. McElroy, Albany, N. Y., 608,343. Filed April 6, 1896. Comprises a central core piece carrying radial arms at either end, an encircling spring placed about the arms, insulating bars placed upon the encircling springs and extending longitudinally parallel with the core piece, a resistance wound upon the insulating bars and straining the encircling springs against the tension of the wire.

Railways and Appliances:—

ELECTRICAL RAIL BOND AND METHOD OF SECURING SAME IN PLACE. W. R. Cock, Plainfield, N. J., 608,178. Filed Dec. 7, 1897. Employs bond terminals which may be formed with or secured to the bond proper, and are formed, with a slight conical contour, so that they can be driven into a perforation in the rail and a comparatively tight joint formed between the rail and terminal.

ELECTRIC BOND FOR RAILWAY RAILS. S. H. Harrington, New York, 608,258. Filed Dec. 10, 1896. Comprises a bond ferrule adapted to enter and fit in a rail perforation combined with a bond-body passing through and movable in the ferrule, the bond-body having its extreme end slotted and a wedge arranged to lie in the slot and spread the end of the bond-body.

TROLLEY. F. E. Case, Schenectady, N. Y., 608,261. Filed June 30, 1897. Comprises a base, a combined lifting and buffer spring extending in one direction only from the base, and a pole-socket pivoted to the base at a point below the centre line of the spring.

SYSTEM OF TRAIN CONTROL. F. W. Rice, Jr., Schenectady, N. Y., 608,301. Filed Dec. 31, 1897. Means by which motor cars equipped so as to run and be controlled independently may likewise be readily controlled from a single point when joined in a train.

SYSTEM OF TRAIN CONTROL. E. W. Rice, Jr., Schenectady, N. Y., 608,302. Filed March 26, 1898. Similar to above.

Regulation:—

REGULATING DYNAMO ELECTRIC MACHINES. C. P. Steinmetz, Schenectady, N. Y., 608,309. Filed April 23, 1898. A method of extending the stable working range of dynamo electric machines, which consists in artificially increasing the reluctance of the magnetic circuit at a predetermined flux.

Switches, Cut-Outs Rheostats, Etc.:—

INSULATING CASTER AND ELECTRIC SWITCH COMBINED. A. W. Slayton, Tecumseh, Mich., 608,234. Filed May 18, 1898. Comprises a wheel made of glass combined with a metallic contact-arm pivotally secured to its metallic frame and adapted to form an electric connection with the floor.

Telegraphs:—

TELEGRAPHIC TRANSMITTING AND RECEIVING APPARATUS. B. Hoffman, Paris, France, 608,333. Filed May 5, 1897. Printing telegraph system. Details of construction.

RAPID TELEGRAPHIC TRANSMISSION ON CABLE LINES. C. L. Davies, London, England, 608,380. Filed June 25, 1896. Details of construction.

Telephones:—

TELEPHONE TRANSMITTER ARM AND ITS ATTACHMENT. W. J. Barr, Ashtabula, Ohio, 608,504. Filed Oct. 30, 1897. Comprises a base for a transmitter-arm having a slotted apex or open mouth, and provided with trunnions for the arm which are arranged interiorly and oppositely in the mouth and have enlarged heads or circumferential flanges.

The Canton Steel Roofing Company.

It is a mistake to suppose from the name "roofing company" that the goods manufactured by this extensive establishment are confined wholly to roofing materials. It is true that this class of goods comprises a very large part of the output, but the products are designed for every use in which architectural effects are sought and for which sheet metal goods are adapted. These uses are many and are coming to be recognized as very desirable, as they have the advantage of cheapness and durability, also being proof against fire and free from dust and vermin, while a very important factor and one that appeals strongly to builders is the immunity of metal construction from lightning stroke, it being stated that there is no record of such buildings ever having been damaged from electric atmospheric

ONE OF THE PRODUCTS OF THE CANTON STEEL ROOFING COMPANY.

discharges. In an especial manner does this material lend itself to the requirements of car houses and power stations, the latter both for street railway and electric lighting purposes, and in these may be included not only the exterior but for the interior finish of the executive offices, and waiting rooms for employees and patrons. A list of the products of the above concern embraces roofing, made from either painted or galvanized plate, and includes plain sheetings, put on with different types of seams, crimped edge, beaded and corrugated as well as imitations of cluster slate, cluster shingles, and steel shingles of different patterns, including the Cushman, Eastlake, and Gothic tile. Included in the roofing materials are cresting block as well as skylights and ventilators, dormer windows, hip caps, tower ornaments, chimney tops, and last but not least, weather vanes and finials.

The above designs are classed as roofing, but the fronts,

which may be either of galvanized or copper plate, include imitations of weather board, pressed brick, and shingle siding, rock faced brick and rock faced stone of either uniform or rambling design, corner finish; pilasters, to which may be added rock faced window and door caps, as well as sills, also bay windows and all designs of cornice with fireproof blinds, either plain or corrugated. There may also be included in the external finish eave troughs, gutters and conductor pipes, either round, corrugated or square expanded, together with cut off joints and fastening accessories. The making of cornice is a large industry by itself, for metal cornices are adapted to all classes of buildings other than those built of metal, and the designing of these requires a high order of architectural talent, a claim which the output from this department has long sustained. Allied to the cornice are the zinc ornaments of which the works produce an almost endless variety.

Material for interior finish includes the ceiling, side wall and wainscoting. Sheet metal is especially adapted for this purpose, as it lends itself readily to the molding process, is preferable to other material because more beautiful, requires no repairs, and will not crack, warp, fall or burn. In this line of goods the company takes especial pride, not only in furnishing original and pleasing designs, but also in the superiority of finish, insuring that the plates will lap straight and regularly, and facilitating the labor of laying and decorating. Continuous styles for interior finish are made in strong relief and panel styles in three different depths.

The metallic buttons and ceiling nails are also provided for fastening plates to the sheeting or furring. The interior plates include beside the above, cornices, friezes, moldings, borders, dados, and ornamental centre pieces.

The output of the factory also includes among the specialties a large number of sheet metal boxes of peculiar designs and different sizes, for use by the customers in safe deposit vaults. These are painted and ornamented and provided with covers and locks. Among the specialties may also be included stove pipes which are made in five sizes. These are unriveted and are constructed with special hook seams which can be hooked or unhooked at pleasure, thus entirely doing away with the "profane annoyances" that have heretofore been a necessary accompaniment in "setting up stoves." These are packed in nests for shipping, insuring a low freight rate. Another unique product is a self-basting roasting pan made in different sizes of stamped metal.

The works of the company occupy a group of substantial two-story buildings, having a ground plan of 210 x 160 feet, and fronting on Tuscarawas street. The tool equipment is especially fine, and is operated by a 40 h. p. engine. There is also a generator for electric lighting purposes. Among the special tools may be noted heavy multiple toggle presses for corrugating and beading sheet metal; the press process being preferred to the rolled for the reason that the sheets are not as likely to buckle and are left in better shape for lapping and seaming.

There are several large drop hammers for stamping panels and for making zinc ornaments, and in these the lower dies are usually made of cast iron, while the upper dies are cast from zinc and combined with the heavy cast iron hammer heads, deliver a very powerful blow. Designs are originated in the draughting room, and they are then wrought out in relief in clay or putty, when from these, plaster of paris patterns are made, numbered and stored for future use. From the plaster of paris patterns the working dies are cast, and these when broken or worn, are re-melted. Band saws and shears operate as auxiliaries to the drop hammers, and on these the sheets are re-trimmed, and in the case of the saw, a number of sheets are faced at one time. The sheets designed for plain roofing after being painted are united in 50-foot lengths by a peculiar interlocking cross seam, and for this work special machinery is provided. On one machine the ends of the plates are folded, then slid together, and as the seam passes under a press in the process of rolling up the metal, the seam receives a heavy blow from a die which closes it very tight. A number of paint grinding machines are provided, in which the metallic oxides are ground in linseed oil. There is also a machine for mechanically applying the paint to the sheet. This is done very rapidly and evenly. The machines for rolling and beading the eave troughs, and for corrugating the conductor pipes are original and interesting, doing the work very rapidly. The cornice and

skylight departments are also equipped with numerous labor-saving devices. On the design for skylights the company prides itself. These are so constructed that the condensation from the glass is carried by gutters in the sash bars direct into the curb and discharged through weep holes on to the roof.

Because of ample facilities and attention to new and approved styles with special attention to quality, design and workmanship, the company have secured a large patronage for their various lines of goods, and their customers are from all parts of the globe.

The affairs of the company are conducted by the president, W. W. Clark; J. A. Shanafelt, secretary and treasurer, and T. C. Belding, superintendent.

Standard Electric Clocks.

THE New York Standard Watch Co., 11 John street, New York, have, after years of careful experimenting, succeeded in perfecting an electric clock movement that is said to overcome all the difficulties existing in the past. The ordinary sealed dry cells, as used for door bells, etc., furnish motive power to the clocks. They are concealed within the clock case, and when exhausted after a number of years may be renewed at the small expense of about 25 cents. The movements run equally well with weak as with strong batteries, automatically compensating for fluctuations in strength of current. They are regulated in the usual way, by raising or lowering pendu-

STANDARD ELECTRIC CLOCK.

lums to increase or decrease rate. One of these clocks, illustrated herewith, gives but a faint idea of the beauty of design and finish of the case. The movement of the clocks is extremely simple, consisting of an electro-magnet, and its armature so arranged as to give occasional impulses to the pendulum whenever an automatic switch closes the battery circuit. These impulses do not occur at even intervals, but their frequency varies with variation in the strength of the current. Therein is claimed to lie the secret of the company's successful adoption of electricity for time keeping. The clocks are thoroughly adapted for use in stores, offices, factories, schools, public buildings and railroads.

Penn Electric & Manufacturing Company.

AS an example vindicating the law of demand and supply, this company has come into existence. It is noticeable that when there is a demand on the part of any considerable number of people for a labor saving or money saving device, or for higher efficiency in machines already on the market, somewhere, and usually from some unknown quarter, just the thing that is required comes forth, so in noting the products of this firm, we find some things that are new, and others that are simplified, or perfected forms of older types, but which seem to be just what the conditions require. These products embrace both electrical and mechanical specialties. The former include switches having capacities varying from 15 amperes up to 5,000 amperes; also switchboards made from either marble or slate, with all necessary connections. One of these consists of a new and patented design, known as a combined switch and distributing board, by means of which all the lights on any floor can be cut out, or all in the building by a single throw of the lever, in case at any time it is found necessary to protect the wiring from a threatened heavy current, either from lightning or crossing of wires. The wiring of these boards is very simple, and provision is made so that the connections are invisible. This is accomplished by providing a hollow binding post, or one that has been tapped into from the under side, so that the wires are inserted and when the cap is adjusted it comes in contact with the core and the wire, making a very neat job. All the binding posts and all connecting parts are cut from solid bars, no cast metal being employed. Other electrical appliances include telephone parts, with the exception of coils and bells, also an adjustable or expanding wire guard for protecting incandescent light globes. This guard, in place, clasps the globe all around, but is so designed that it parts at the base, so it can be unfolded to a flat circle, and when so unfolded the globe can be readily removed and renewed, when the guard is again closed in place. These guards are also made double, so that the outer one may be expanded and serve to carry a lamp shade, while the other protects the globe.

Among new mechanical devices, and one for which the company finds a great demand, is an adjustable door lock, by means of which a door may be fastened open at any angle, and still locked in position from the inside. This lock consists of a curved, perforated flat bar, so fitted to the jamb of the door that it plays freely in a locking device at the top of the door, the door being held in any position by a pin that is actuated by a chain hanging against the door on the inside. The most interesting mechanical device, however, which is made by this company, and which is in practical use in the shops, is an adjustable belt shifter, or rather a speed regulating device that avoids the shifting of belts. This device consists of a pair of expanding pulleys, one on the main shaft, the other on the jack shaft, or the one from which the machines are driven. This pulley when contracted has the form of an hour glass, but when closed looks like an ordinary pulley with a V-shaped groove. It is actuated by a shifting mechanism, which is operated by a vertical rod within easy reach of the operator. By turning this rod the pulleys may be simultaneously adjusted; one opened, and the other closed, thus giving any desired change of speed, without affecting the tension on the belt, a V-shaped belt being employed. These pulleys consist virtually of a pair of cone-shaped pulleys, with alternate triangular-shaped sections cut in the face of each so that they may dovetail together. One of each pair being fastened to the shaft, the other is made to approach or recede while running, and the speed graduated accordingly. There is also provided a means for tightening the belt by shifting the bearings of the secondary shaft. This device is said to be durable, and is not very expensive.

The company also make a specialty of chandelier fixtures for both electric and gas service, and they make many kinds of special machinery and tools, including patterns, models and perfected machines for inventors and engineers.

The shops are located on North avenue, Wilkesburg, Pa., and the tool equipment of the factory is especially fine, consisting of the latest designs in turret headed lathes, milling machines, with a complement of ordinary metal working lathes, planers and drill presses, including one gang press. There are also tools for cutting and drilling marble and slate, with the necessary wood-working tools for pattern making, all of which are driven by steam power, generated on the premises. The business, however, has outgrown the capacity of the works, and the company

contemplate moving to a more commodious building in the near future, or will erect for their own use extensive works that they may keep up with the demand.

The official staff of the company consists of the president, Mr. Fred. Hockensmith; secretary and treasurer, W. F. O'Neill, and D. M. Wagner, while the active management is in the hands of Mr. J. A. Wright, the originator of the company, and patentee of many of the specialties.

A New Combined Fuse Block and Lightning Arrester.

THE Telephone Department of the Electric Appliance Company, Chicago, has just put upon the market a combined fuse block and lightning arrester. It is an article of merit and will demand the attention of telephone exchange managers. It is four and one-quarter inches long by one and one-half inches wide. The illustration herewith gives a very fair idea of its appearance. Absolute protection is secured, it is claimed, from burn-outs from crosses caused by trolley and electric light lines breaking and falling across the telephone wires. It is also a positive lightning arrester and is practically indestructible. It requires no attention. The effect of a lightning discharge across the carbon blocks is that of producing a small amount of carbon dust. This can easily be removed by pulling out the carbon

COMBINED FUSE BLOCK AND LIGHTNING ARRESTER.

blocks and blowing out the dust, then replacing them, and the arrester is in working order again.

The fuse end of the arrester is connected to the wires running to the instrument to be protected, and the carbon arrester end is connected directly to the line wires.

The lightning arrester, part of this block, is constructed with two carbon blocks with perforated mica separating them. One block rests on the ground plate and the other is connected directly on the line, the idea being to produce an arrester on the air-gap principle. The perforations in the mica separator produce this result when the carbon blocks are placed in their proper position on the arrester. The fuse portion of the arrester can be furnished with either the Postal or Western Union type terminals, an ordinary two-inch copper or foil terminal fuse being used. The base is made of porcelain.

Montauk "Multiphase Cable" in Australia.

The popularity and success of American electrical goods abroad is shown again by the following item from the "Advertiser" of Williamstown, the port of Melbourne, Australia, of July 2d:

Yesterday afternoon a number of leading gentlemen attended Mr. E. H. Kirkby's manufactory, Nelson Place, to witness some startling effects in electric mechanism, either introduced into the colony from America by Mr. Kirkby, or the results of his own researches. The public of Williamstown may not be aware that Mr. Kirkby, in his own special line, is not only the leading mechanic in Melbourne, but he perhaps has no equal in Australia. He does the electric alarm work for the Metropolitan Fire Brigade; has fitted up Government House, several of the large houses in Flinders Lane, the Princess Theatre, and his services have been sought to do similar important work in Sydney.

Mr. Kirkby yesterday astonished his visitors by the readiness of the various devices in his establishment to give fire alarms and ring bells and telephones upon the slightest provocation. There would be a fortune for an illusionist show in some of this mechanism he uses. One of these is so sensitive to heat that by

merely breathing upon it it will ring an alarm bell; but Mr. Kirkby explained that the temperature at which it worked could be regulated like the working of an alarm clock.

Mr. Kirkby has introduced the Montauk multiphase fire cable into the colony, and it was submitted to a highly satisfactory practical test for the first time in Australia yesterday. It is a most ingenious invention and Mr. Kirkby is so satisfied with it that he has taken the responsibility of recommending it to Mr. Stein, superintendent of the Metropolitan Fire Brigade, and will introduce it to the big mercantile houses in the city. The cable can be attached to an ordinary electric bell, to a telephone and to the fire alarm. The great and peculiar property possessed by this cable is that when it is ignited it will instantly ring a fire alarm on any premises where Mr. Kirkby's automatic fire alarm is connected with it. Mr. Kirkby is convinced that if this cable had been used in Melbourne recently the great fire at which damage to the amount of nearly one million sterling was done would have been avoided. Mr. Kirkby intends to give another demonstration in the city at an early date.

Simonds Manufacturing Company, Pittsburg.

THE principal products of this firm are pinions and gears for electric motor cars, and these, next to the motors, are the most important factors in electric car propulsion, for although the former are necessary to transmute the electric energy into power, they must needs deliver it to the axles and wheels through the medium of pinions and gears. As this service is particularly trying, the material, design and workmanship must needs be of a high order, and so exacting are the requirements of this service that only a few manufacturers, comparatively, find it possible to compete for this trade. This firm, however, because of long experience had in the business by one of the principals, and because of ample facilities, are turning out a first-class product, and are continually filling large orders, both for home consumption and from abroad. Two kinds of gears are manufactured, one from malleable iron, the other from steel casting, but in both cases a special mixture of material is specified, and the same grade has been maintained since its adoption in 1893. The castings are made in two parts, which are virtually split pulleys, with a smooth rim, and a single arm or spoke, which when fitted serves to bolt the two portions into a solid wheel about an axle. The machine work on the blanks consists first in planing the face of each spoke of a pair, including the hub, to provide for an exact fit, and this work is done on milling machines, in which the two halves are placed side by side, face up, and are dressed at the same time from milling tools on the same shaft, one cutting what is termed the male, the other the female face. The arms are then drilled, and the halves are bolted firmly and accurately together, when the hub is bored out, and next the gear teeth are cut. Two at a time are cut on milling machines, a very great degree of accuracy being required to prevent noise when running, and any undue strain from a lack or excess of metal in any one of the teeth. The malleable gears are more generally in favor with street railway managers than those of steel, and the company point with pride to a record of life of two years and a half made by one of their malleable gears on one of the street railway lines of Pittsburg. The pinions are cast in solid blanks and are then bored out and the gear teeth milled as described above.

The shop equipment is not devoted entirely to the manufacture of gears and pinions, but the company take orders for special work, and for gears and pulleys of every description. They also build the Murphy wheel grinding machines, which are having a large sale, and they also are building the large jacks and gears and other parts for the two dismantling devices to be employed in the new repair shops of the Consolidated Railway of Pittsburg, which were described recently in *The Electrical Engineer* in connection with that system. Another very interesting machine which has been designed and is being manufactured by the firm, is a glass bottle moulding machine, in which glass jars or bottles can be made at the rate of five a minute.

The works of the company are located at the corner of Liberty Ave. & Twenty-fifth Str., Pittsburg, Pa., and occupy a large two-story building with a fine heavy tool equipment, in which thirty to fifty men are employed. An elevator connects the two floors, and there are two traveling cranes for handling the large work. One of these has a span of 26 feet, and a run of

100 feet. The tools that are devoted exclusively to the manufacture of gears and pinions have a capacity for turning out twenty-five gears a day.

The management of the company's affairs is in the hands of Mr. Biddle Arthurs, president, and John Jackson, superintendent.

Leonhardt Wagon Manufacture Co., of Baltimore.

A railway emergency tower wagon for making trolley repairs is one of the special products of this firm, and quite a number of these wagons are in use by the local street railway companies, this type of wagon being the principal equipment of all the trouble stations of the principal railway systems of Baltimore. The particular feature of this wagon is a revolving base for the tower and the overhanging platform, as is shown by the accompanying illustration, by means of which repairs can be made without blocking the line. When in posi-

RAILWAY EMERGENCY TOWER WAGON IN POSITION FOR MOVING.

tion for moving, the tower is lowered upon the body, but does not extend above the driver's head nor does it overhang beyond the body in the rear. To be placed in position, the platform is first raised up by hand, then by means of sprocket chains, actuated by a crank shaft and gears, the tower is raised to a perpendicular position, and then by means of a second shaft it is extended after the manner of an extension ladder. It is easily raised and lowered by one man, and is not top heavy. Perfect insulation is provided, and the body is equipped with

TOWER RAISED OVER PASSING CAR.

large and roomy compartments for tools, including a cupboard under the driver's seat with doors on each side and a shallow box for tools, which constitutes the seat proper. The body is mounted on platform gear, and can be turned in its own length. A light tower wagon is also manufactured for use on roads having only light traffic. This has only tower ladders, without the revolving platform, and without operating mechanism. The ladders are raised by hand, and when up, the rear ladder is braced upon an elevated rod above the body upon which it rests by a forked foot, a pin being inserted below the rod to keep it always in safe position.

These wagons are well built, receiving the same care in construction as is given to the manufacture of the fire department wagons, including hose and "chief" wagons, of which the firm manufacture a large number, and well as wagons for all business purposes.

The shops occupy two brick buildings, one 25, the other 45 feet, by 225 feet deep, with a lumber yard of the same depth, 25 feet in width, between them. The manufacturers claim to have the best oak and hickory that is to be found in Maryland, as they are located in the neighborhood of the finest hard wood section of the country, and they are thus able to turn out first-class work at moderate prices.

Tests of Beacon Lamps.

A few weeks ago we had occasion to call attention to the high grade lamps turned out by the Beacon Lamp Company, of New Brunswick, N. J., noting how remarkably they retain their initial candle power and high efficiency after a run of 300 hours. The standard efficiency of the lamps is 3.5 watts per candle, and it is an actual fact that after 300 hours' burning the lamps give more light and use less current than when started, and show no blackening. These statements have been substantiated by tests made at the company's factory, and they now invite any trustworthy person to make photometric and other useful tests on their lamps and they will find that the company's claims are true. The following is one of a number of tests tried. Several Beacon and other lamps were burned side by side. After 200 hours' run half of the Beacon lamps were replaced by an entirely new set of the same make, and it could not be distinguished which lamps were the old and which the new ones. They have sent several batches of lamps to educational institutions for tests, and the results of these tests will soon be published by the company.

Activity of the Walker Co.

A contract awarded to the Walker Company, of Cleveland, for alternating current electric generators, was told of a few weeks ago. This order consisted of twenty 500 horse-power generators with other apparatus for the Union Carbide Company, of Chicago, and was in itself the largest single order for machinery of the alternating type ever placed. Mr. S. H. Short, vice-president of the Walker Company, has, during a recent trip to Chicago, secured a duplicate of this contract from the same company. The order as it stands comprises over 20,000 horse-power in generators and forms the largest contract for electric machinery of any kind ever awarded. The shops of the Walker Company are running night and day on existing orders and the recent large additions to the plant will be taxed to their utmost to put out the immense amount of work already in hand.

An Order from Australia.

The Government of Victoria, Australia, has placed an order with the General Electric Company for six Thomson recording wattmeters of 100 volts and varying capacities. These will be deposited in the Electrical Bureau of the Home Office of Victoria and will be used as the official standards by which all electricity meters used in the colony will be tested. In future no meters measuring electrical energy will be allowed to go into service in Victoria unless they agree with those just ordered and receive the final sanction of the Victoria Government.

Samson Batteries in the West.

The Central Electric Company, of Chicago, who are acting as Western distributors for the various types of Samson batteries, report a large and continuously increasing use of this product. The Samson battery has attained an enviable reputation as a product for use under conditions requiring the most exacting service. There has been quite recently introduced the new Samson "semi-dry battery," which has become very popular by reason of its desirable features. This battery has extra heavy zincs and large carbons contained in a porcelain jar and sealed. Its ampere output is very large, and as it is portable it is adapted for use under conditions where the former type of open batteries could not be used. The Central Electric Company are carrying large stocks of all Samson types and are prepared to make immediate shipment on all orders.

PINE BLUFF COTTON OIL CO., Pine Bluff, Ark., has recently ordered an engine for electrical purposes from the Ball Engine Co., Erie, Pa.

First Order From Our New Dependencies in the West Indies.

The Westinghouse Machine Company have already begun to reap some benefit from the recent brilliant successes of American arms in Cuba. They are to-day advised that their New York office has received the initial order for a complete steam plant, involving a 100-horse-power Westinghouse engine and Westinghouse generator, together with boiler, pump, piping, etc., this plant to be installed in Santiago de Cuba.

Warren-Medbery Company.

The new works of the Warren-Medbery Company, manufacturers of inductor alternators, Sandy Hill, N. Y., are now running to their utmost capacity, day and night, in order to fill the orders for their apparatus. Their business has increased over 100 per cent. within the last sixty days, the demand for inductor machines reaching far beyond their expectations. They have recently made a large addition to their works, and the new machinery is now being installed, when they hope soon to be able to meet all demands upon them, for alternators. They are also manufacturing a fine line of standard white marble switchboards, and a full line of the celebrated "Medbery" and "Standard" switches, so well and favorably known. The "Medbery" insulation and over-head equipment, for electric railways is now being manufactured by this company, who are prepared to furnish this high grade material promptly.

Fuel Economizer Sales.

The Fuel Economizer Co., of Matteawan, N. Y., find business excellent and improving. They report recent sales as follows: Milwaukee Electric Railroad, Milwaukee, Wis., 2,000 h. p.; Worcester Bleach and Dye Works, Worcester, Mass., 350 h. p.; Merchants' Cotton Co., St. Henri, P. Q., 600 h. p.; Excelsior Mills, 300 h. p.; Lehigh Valley Coal Co., Wilkesbarre, Pa., 2,000 h. p. (2 orders); Western Cold Storage Co., Chicago, Ill., 300 h. p.; Cheney Brothers, South Manchester, Conn., 2,000 h. p.; Blackstone Mills, Blackstone, Mass., 500 h. p.; La Belle Mill, Water and Power Co., Goldfield, Colo., 1,000 h. p.; Dominion Cotton Mills Co., Mago, P. Q., 1,000 h. p. (12th order); Frick Co., Waynesboro, Pa., 150 h. p.; D. M. Bare & Co., Roaring Springs, Pa., 600 h. p.; Rome Brass and Copper Co., Rome, N. Y., 350 h. p.

Frontier Iron Works, Detroit.

Among recent shipments of Frontier tandem gasoline engines by the Frontier Iron Works, Detroit, are: One 60 h. p. to Norway, Mich., for a village electric lighting plant of 600 lights; one 40 h. p. to Bay City, Mich.; one 40 h. p. to Ogdensburg, N. Y.; one 40 h. p. to Wichita Falls, and several 25 and 20 h. p. engines of the same type. The company claim for this engine a regulation equal to that of the steam engine, adapting it to electric lighting and similar duty at a decided economy of fuel and attendance.

ADVERTISERS' HINTS

THE PECKHAM TRUCK CO. call attention to their extensive line of trucks adapted to all conditions of service and all styles of car, both passenger and freight, and trucks also for switching engines.

TELEPHONE WOODWORK is the subject of the announcement of the Cabinet Mfg. Co.

THE WROUGHT IRON BRIDGE CO. advertises iron and steel bridges, buildings, roofs, turn tables, etc.

F. A. LA ROCHE & CO. specify the Ideal Circuit Breaker as the king of all instruments of this nature, at the same time announce a new circuit breaker, the Victor, which will shortly be placed on the market.

WILLIAM E. QUIMBY advertises screw steam pumps.

BEACON LAMP CO. guarantee their lamp to maintain initial candle power for over 300 hours.

"CHEAPER THAN COPPER" bids fair to be the trade-

mark of John A. Roebling's Sons Co. in connection with "Bi-metallic Wire."

WHEELER REFLECTOR CO. offer their reflectors as the connecting link between sunset and sunrise.

WESTINGHOUSE ELECTRIC & MFG. CO. show illustrations of four different types of their engines.

WESTERN NOTES

F. & L. PUSH FLUSH SWITCH is one of the most successful of the Electric Appliance Company's smaller specialties. It is the smallest push switch on the market, the size of the face plate being only $1\frac{1}{4} \times 3\frac{1}{4}$ inches. It also requires a very small opening in the wall, operates with a very slight pressure on the keys and has many other valuable features, not the least of which is the fact that it is sold at a price considerably below the market for a push flush switch.

THE CITY OF ELKHORN, WIS., has recently ordered a 135 h. p. compound condensing engine for its electric plant. The engine will be furnished by the Ball Engine Co., Erie, Pa.

MR. J. G. HICKCOX, secretary of the Cutler-Hammer Manufacturing Co., 70-82 West Jackson street, Chicago, says: "Our business has increased so rapidly in the past few months that we have been obliged to secure additional space which we are equipping with the latest machinery. With these improved facilities we expect to be able to take care of all orders in a prompt and efficient manner."

CARD ELECTRIC CO. Mr. S. N. Ford, receiver of the Card Electric Co., of Mansfield, Ill., reports with regard to their recent situation as follows: "The immediate cause of our embarrassment was too much work. We accumulated a large number of orders and found ourselves unable to put them through our factory fast enough to meet our obligations for material, and had to take action to protect ourselves and creditors. We expect to continue work without interruption."

CENTRAL ELECTRIC CO., of Chicago, is issuing a very attractive circular on various types of electrically heated cooking utensils and appliances, and will be pleased to send the same to anyone on application.

CEDAR RAPIDS, IA. As the result of an investigation by the City Council of prices in different parts of the country, a contract has been recommended with the Cedar Rapids Electric Light and Power Company for ten years at \$75 per year per 2,000 c. p. arc light, 210 lamps being required. It was shown conclusively that this price was hard to beat.

NEW ENGLAND NOTES

PAGE ELECTRIC CO., of Worcester, Mass., has recently increased its capital stock to \$5,000. It has bought out the business of the Worcester Central Electric Co., and has established itself at 24 Pearl street. The Page Co. was originally founded in 1885 and incorporated in 1897. It is doing a large amount of construction work, and is selling apparatus all over New England. Mr. J. P. Coghlin, who is well known in the trade, is now treasurer and manager of the concern, and is pushing things.

NEW ENGLAND SANITARY PRODUCT CO. are erecting at Old Harbor Point, Mass., near Boston, an absolutely fireproof building 120 feet wide and about 130 feet long. The building is two stories high, and is of skeleton steel framework style, consisting of steel columns built in the walls, carrying heavy steel floor beams and girders, and clear span roof trusses which support the roof. The structural steel work in this plant was designed and is being furnished and erected by the Berlin Iron Bridge Company, of East Berlin, Conn.

MECHANIC FALLS, ME., has a prodigy in Henry E. Rowe, who at the mature age of seven is a good telegraph operator.

WORCESTER, MASS. The Page Electric Co. has absorbed the business of the Worcester Central Electric Co., and has moved to new and larger quarters at 24 Pearl street.

NEW YORK NOTES

DOVER, N. Y. The new manager of the Dover Electric Light Company is Mr. Eugene T. Wightman, from Middletown, N. Y., where he was the chief engineer of the Middletown-Goshen Traction Company. Prior to that he was with the Electric Street Railway Company in Danbury, Conn., and for ten years he was the superintendent of the electrical department of the Danbury-Bethel Gas and Electric Light Company.

MR. ROSSITER, president of the Brooklyn Heights Railroad, has proposed a trolley loop one mile around on the New York side of the bridge, to avoid the present congestion. It is the same old trouble. What is wanted is a few more bridges.

The Electrical Engineer.

Vol. XXVI.

AUGUST 25, 1898.

No. 538.

The Snoqualmie-Seattle-Tacoma Transmission With Aluminum Live Wire.

SECOND to none in importance among the water power transmission projects that are being carried out this year is the undertaking which will bring the water power of the Snoqualmie Falls to the cities of Seattle and Tacoma, Wash. It is expected that within a few months this company will be able to furnish 4,000 kilowatts at Seattle, and 2,000 kilowatts at Tacoma, the latter city being the most distant from the falls. The company is backed by Chicago capital and brains, William T. Baker, formerly president of the Chicago Board of Trade, being the financial backer, and Thomas T. Johnston, a prominent Chicago engineer, consulting engineer of the drainage canal, and president of the Western Society of Engineers, engineer of the new project, under whose direction the work has been planned and is being carried out. Chas. H. Baker, of

ledge of rock at that point. The dam will be 450 feet long, fifteen feet wide at the base, eight feet wide at the top, and of solid concrete. In the centre of the dam will be a bear trap dam for the escape of flood water. The water intake will be a 20-foot channel extending 60 feet up and down stream. From the intake the water will be piped through two 7-foot steel pipes down a vertical shaft cut down 250 feet in the solid rock. The shaft is being cut 25 by 8 feet. The water wheels and generators will be in a cave at the foot of the shaft, 200 feet long, 50 feet wide and 25 feet high. A tunnel is being driven in horizontally from below the falls to serve as a tail race. This tail race will extend from the wheels, 660 feet to an outlet in the face of the cliff below the falls. In order to clear the river for the building of the dam, the current will be turned through the shaft and tail race as soon as they are finished and allowed to run there until the dam is finished. In other words, Snoqualmie Falls will go dry for a time. The rock taken from the shaft is being crushed for use in the concrete dam. The dam being completed, the current will again be turned into the river, and Snoqualmie Falls will again exist. Then the two steel pipes and an elevator will be put in the shaft, and the water wheels and dynamos placed in the cave at the bottom. There will be four 1,500 kilowatt, 1,000 volt Westinghouse three-phase generators with a frequency of 7,200 alternations per minute. They will be direct connected to water wheels running 300 revolutions per minute. These generators are to be of the revolving armature type.

MAP OF SNOQUALMIE FALLS TRANSMISSION.

The current will be conducted at 1,000 volts to the top of the shaft where the switchboard and static step-up transformer house will be located.

The full load voltage for the transmission line will be 29,000 at the Falls, and 25,000 at points of delivery. This will probably be the first large transmission plant to start with such a high regular working voltage. By altering the method of connecting the step-up and step-down transformers, the voltage can be reduced to 21,000 with a correspondingly greater loss in the line, but without interfering with the power consumers' voltage at Seattle and Tacoma.

For the first twenty miles the transmission lines to Seattle and Tacoma will run over the same right of way. At Renton, they separate, and one goes northwest about twelve miles to Seattle, while the other goes southwest about twenty-seven miles to Tacoma. At Renton there will be facilities provided for switching the Seattle circuit onto the Tacoma circuit and vice versa.

The company has decided on the use of aluminum wire for the transmission line, Engineer Johnston being authority for the statement that "We have succeeded in making contracts for a supply of aluminum wire at prices that make it cheaper than copper for our purpose. The metal we are to use will be of remarkably pure quality, being guaranteed to contain 99.30 per cent. of aluminum, and not more than 0.25 per cent. of iron and 0.30 per cent. of silicon. This will be alloyed with 1.50 per cent. of pure lake copper. We shall use about 150,000 pounds of it."

This is the first large transmission to use aluminum, and marks an important step in electrical engineering, for while aluminum has been talked of for some time for this purpose, price or some other factor seems to have stood in the way of its practical use to any extent over long distances.

Seattle, is president and manager of the company, while J. J. Reynolds, formerly chief engineer of the Chicago Terminal Railway, is superintendent of construction.

The falls of the Snoqualmie River are about twenty-four miles (air line) east of Seattle, and thirty-four miles (air line) northeast of Tacoma. The Snoqualmie is fed by the western slopes of the Cascade range and drains about 400 square miles. The falls have a drop of 268 feet. Readers of The Electrical Engineer will remember the picture published of the falls in these pages, four or five years ago.

Construction work began early the past spring. Three hundred feet up the river from the falls a dam will be built along a

The pole line is for the most part on the country roads, but in some cases a private right of way has been secured for a small sum. Large trees liable to fall on the line have all been cleared away. The poles were all purchased in the surrounding country. Wooden pins and cross arms will be used. Two circuits of three No. 2 aluminum wires each will run to Seattle, and two circuits of three No. 3 aluminum wires each will run to Tacoma. Thus each pole line will carry six wires. There will be two cross arms on a pole and the pins will be arranged so as to bring the three wires of each circuit at the corner of an equilateral triangle. Triple petticoated porcelain insulators known as the Redlands type because used on the Redlands, Cal., transmission, will support the aluminum conductors. Poles will be set about 120 feet apart.

Like other companies developing large water powers for electric transmission purposes, this company will aim to do a wholesale rather than a retail power selling business, and will sell mainly to existing companies in the light, power and railway business. Already a large output has been contracted for. Coal in Seattle and Tacoma is cheap, being about the same as in Pittsburg, but it is of such poor quality as to be of only about half the calorific value of Pittsburg coal.

The flow of the Snoqualmie River is such that 30,000 horse power will be available at extreme low water, but a system of catching flood water might increase this many times, should it ever be demanded by the needs of the two cities. About 12,000 horse power is to be made immediately available at the falls, according to the present work being carried out.

The Enlargement of the Niagara Power House.

BY O. E. DUNLAP.

FIVE of the great 5,000 h. p. dynamos now stand in a row on the floor of the power house of the Niagara Falls Power Company, and the sixth one is being built in front of the new switchboard. The original switchboard is designed to handle the current from only five of the machines. The new switchboard structure stands at the far end of the dynamo room, and is similar in design to the first structure. Each board will control five of the dynamos to be placed. The illustration well portrays the present appearance of this famous station.

Over in the transformer room there are eight of the transformers in position, all of the same pattern.

A short time ago the Buffalo Railway Company installed another pair of rotary converters to handle Niagara current.

EXTENSION OF THE NIAGARA POWER HOUSE.

Their design is similar to the machines first placed. The Buffalo Railway Company are now taking 2,000 horse power of the Niagara current.

That there is a growing demand for Niagara power in Buffalo is evident from the fact that the Cataract Power and Conduit Company are building a new transformer station at No. 2290 Niagara street in that city. The building will be of brick, and cost \$2,500. It is understood that a large malt house that is

being built at Niagara and Albany streets, Buffalo, will receive the first power from this station. This malt house will have a frontage of 340 feet on Albany street and 220 on Niagara street. It will have a capacity of 300,000 bushels. There will be thirty

STEP-UP TRANSFORMER BANKS, NIAGARA POWER HOUSE.

pneumatic tubes, each with a capacity of 600 bushels. A kiln 60 feet square and 180 feet high will also be built in connection with the malt house.

Individual Motors for Coil Winding in a Telephone Factory.

THE American Electric Telephone Company, in its factory at Chicago, one of the largest independent telephone concerns in the United States, has adopted a subdivision of electric power units for winding coils that carries electric shop transmission and subdivision to an extreme rarely found. The interest in this transmission lies, not in the simple fact that electricity and the electric motor are the means employed for delivering power to the different machines, but in the smallness of the motors and the fineness of the subdivision.

In the department of the factory where the various coils are wound, are a large number of small motors—one for each operator employed in winding. Thus, instead of having a winding lathe for each operator and connecting the lathe with a line shaft, each operator has a small motor and the core to be wound is put directly on the shaft of the motor. The company made its own motors for this purpose. They are of an entirely enclosed type to avoid all danger of accident or injury to the motor as the operators are working over the motors. The motor is, of course, put on the bench in front of each operator. Just at the edge of the bench, at the operator's right, is a rack for holding the supply wire spool. The core to be wound is put on the right hand end of the motor shaft and the wire is run directly from the spool to the core through the operator's right hand, which acts as a guide and a brake to keep the wire tight in winding. At the left hand end of the motor shaft is a disc about four inches in diameter for a hand wheel by which the motor shaft can be held or turned by the operator when putting on or taking off a core, or when starting or ending a coil. Just under the bench at the operator's left hand is a rheostat protected by perforated sheet brass. While guiding the wire with the right hand, the operator turns on current with the left, and if the operator is skilful, a very high speed is attained in winding. Nowhere is the convenience and flexibility of the electric motor better shown than in this work. Instead being confined to a table equipped with line shaft underneath and cone clutches, the operators can be scattered

around where light is good and where space can be utilized to best advantage. The speed is more perfectly under control than with a common line shaft, and consequently more and better work can be done. Girls are employed at this work.

This is a good example of the extremes to which the subdivision of electric motive power in shop transmission is being carried these days, and shows that mere economy of power is by no means the chief object to be gained by electric shop transmission in many cases. Convenience of location, utilization of waste room and perfection of individual machine control may be far more important factors in the output of a factory, shop or printing office than simple cost of power alone.

Timing Calls in Telephone Exchanges.

BY HENRY ABBOTT.

IT is not proposed in this paper to discuss such interesting questions connected with the handling of a telephone toll department as the length of the initial period or the minimum period upon which a charge should be made; the amount of grace which should be allowed, or the number of seconds a patron may be permitted to talk beyond the first period before he is charged with the second; the question whether all time beyond the first period should be prorated; the number of trunk lines a single operator may handle profitably, etc.; but to consider the relative merits of the different methods and ap-

FIG. 1.

pliances employed in timing calls in telephone exchanges in the United States.

It will be apparent, however, that the success of any method of timing is dependent in a measure upon the number of connections an operator is obliged to make. It is obviously good business policy in the management to require operators to handle as many trunks as they can efficiently and profitably. Local conditions and the character of the business of course affect the number of messages as well as the number of trunk lines which a single operator can handle and supervise closely. Thus, lines connecting cities or large towns are kept "hot" with messages during the rush hours of the day, while lines radiating to the suburbs or connecting sparsely settled communities are less often used, and of this latter class an operator may efficiently handle more trunks than of the former. It is, however, my belief, based upon observation, that there are more telephone exchanges in which the mistake is made of overloading toll operators beyond the point of giving efficient service and the point where it is profitable, than those in which the error is upon the other side.

One manager expressed the situation fully in saying to me,

FIG. 1a.

"our operators are too busy to employ any other method of timing messages than that of writing it down with a pencil." This manager clearly did not understand the situation, was doubtless too busy to investigate or have it investigated for him. He could not know how much revenue his company lost in toll charges because the operator read the time wrong on the clock dial while she was trying to talk to and make connections for two other patrons, or having read it right, wrote it down wrong, or made an error in subtracting the commencing time from the finishing and got the elapsed time wrong; or, as is

most often the case, waited until she had a spare moment, and then having forgotten the actual time, was compelled to estimate it. In such case, the operator being only human, having a wholesome fear of discipline, and knowing full well that only the patron who is overcharged ever makes a "kick," gives the patron the benefit of the doubt in her estimate.

I shall consider as means employed to time toll messages, pointing out the advantages and disadvantages of each, the following: 1st. Clocks having visible dial, hour and minute hands. 2d. Clocks having visible dial, hour, minute and second hands. 3d. Clocks showing figures representing the hour and minute through openings in the face. 4th. Time stamps. 5th. Stop watches. 6th. The calculagraph.

The clock having hour and minute hands only, undoubtedly possesses the advantage of being the cheapest device which could be employed. I have seen in use in a number of exchanges, clocks for timing toll messages (upon the accuracy of which the entire revenue of the department depends) which could be bought at retail for fifty cents, and which purchased in quantity doubtless cost the companies using them very much less. There are, of course, a great variety of clocks available for this purpose. Improved machinery and modern methods have enabled the American clock manufacturers to produce and sell for a few dollars a really excellent time keeper; and in view of the possibilities of the clock market, it would appear that the spirit of economy has been pushed to the point of absurdity when it employs for the purpose of determining the value of a service amounting to perhaps several hundred dollars per day, the meanest and most poorly-constructed device which is entitled to the name of clock.

When clocks having hands or pointers are used for timing messages, one should be provided for each operator and should be placed directly in front of the operator, with the centre of dial in the line of vision. I have seldom seen them so used. It is more common to find one large clock hung high up on the wall used by the entire exchange, or to find one on each side of the room, or at the best, one of the smaller, cheaper variety placed between each two adjacent operators. A serious objection to so placing the clock is the fact that each operator will see the time differently at the same moment; moreover, each operator will see the time incorrectly at different periods and will read it both fast and slow during each half hour. For example, let us suppose that a clock having a six inch dial be placed upon the front of the switchboard midway between

FIG. 2.

two operators, and at such height that it will be central on the line of vision. When the minute pointer is at the top of dial, the operator at the left, looking at the clock, will see under the point of minute hand and the hand will appear to her vision to coincide with the minute mark on the dial from one minute to one and a half minutes faster than the actual time indicated. This is due to the oblique view she gets of the clock face. At the same moment of time the operator at the right will see the time from one to one and a half minutes slow. See Figs. 1 and 1a. Again, when the minute pointer is at the bottom of the dial, the conditions being reversed, the left hand operator will see the time slower, and the right hand operator will see it faster, than the correct time indicated to a person looking directly toward the centre of the dial. See Fig. 2. When the minute pointer stands at either IX or III, both operators will see the time correctly. At all other points on the dial the error of vision is a constantly varying quantity, depending upon the angle of vision.

I recently persuaded the superintendent of one of the telephone companies to make a series of tests of the methods then in use in his exchanges for timing toll messages. The results obtained were a revelation and led to immediate preparation

for reform. It would be manifestly improper to mention names of corporations or individuals in a paper of this character; but I am permitted to state the conditions existing and some of the results obtained.

The test was made on a toll-board having six operators, each of whom handled the business of eight trunk lines extending to towns within a radius of thirty miles; the system of charging was for even periods of five minutes each, and thirty seconds grace was allowed before a charge for an additional period was made. The charge for each period on the lines covered by the test averaged thirty-five cents, clocks having minute and hour hands only being used, and placed between each two adjacent operators.

Inspectors were appointed to "listen in," and without the knowledge of the operators, made duplicate records of the elapsed time for each connection, using stop watches for this purpose. Four hundred connections were so tested, and the elapsed times obtained by listening in compared with the elapsed times written down on the toll checks by the operators.

The results were as follows, viz.: 13 per cent. of the connections were from five to ten minutes in length and $6\frac{3}{4}$ per cent. lasted more than ten minutes. $59\frac{1}{2}$ per cent. varied less than one minute from the time obtained by listening in on connections; the other $40\frac{1}{2}$ per cent., which were more than one minute out, were in every case timed in favor of the patron, i. e., they were not charged with proper overtime. As but seventy-nine of the four hundred connections were of such length to be subject to charge for not more than one period, only thirty-two of these charges were lost to the company,

were cautioned to be very careful to time their connections accurately. Three hundred connections were timed with the following results, viz.: 18.3 per cent. were five to ten minutes in length and 4.7 per cent. lasted more than ten minutes. The time obtained by listening in, when compared with the time written down by the operators, showed that 84 per cent. varied less than one minute each, the other 16 per cent. being over one minute wrong, and in every case, timed in favor of the patron. The three hundred connections represented a total of three hundred and fifty charges. Of this number ten charges were lost to the company because of inaccurate timing by the operators. Should this test be taken as an average showing of the business of this particular exchange, the results would indicate a net loss in revenue (figured upon the average daily receipts) equal to \$11.62 per day.

The manager, however, expressed the opinion that it would be unfair to assume this to be the average, as the operators could with difficulty maintain this standard of efficiency, even though they knew they were being watched.

I have observed it to be the practice in some exchanges for the operator to write on the toll ticket, at the end of a conversation only, the elapsed time in minutes. In others, to write

FIG. 3.

FIG. 6.

FIG. 10.

FIG. 12.

FIG. 11.

At thirty-five cents each, they, however, represented a net loss of \$11.20 on the four hundred connections, or 6.6 per cent. of the total value of the business.

Had the other conditions been the same, but the charges based upon even periods of three minutes each instead of five, it is easy to figure that the net loss to the company due to these errors in timing would have been very largely increased. Or had the distance covered been greater or the tariff charges correspondingly higher, the loss in revenue would have been large enough to merit the attention of the busiest of managers.

Another test was made in an exchange where the conditions were similar to those above stated, and where the same style of clock was employed. In this case, however, the operators were warned that their work was being watched by inspectors, and

the time of day at the moment of connection and the elapsed time at the disconnection. In still other exchanges it is the practice to write the time of day both at connection and disconnection, a special clerk being charged with the duty of subtracting the one from the other, noting down the elapsed time, calculating and recording the charge. This latter system appears to possess advantages over the two others mentioned, in that it relieves the operator (especially in a busy exchange) of the mental strain required to perform such operations of subtraction and multiplication, and would reduce the errors resulting from such calculations to the minimum, though it would not remove the errors of vision, or those of memory, and would, moreover, be impracticable, except in a large exchange, because of the salary of the additional clerk.

In the use of a clock having visible hour and minute hands only, it is most convenient for the operators to ignore all fractional parts of a minute and to record upon the toll checks even minutes only. If then a half minute be dropped from the actual time of connection and another half minute from the

FIG. 7.

time of disconnection, the elapsed time shown upon the toll check will be a full minute less than the actual time of the conversation. It might be assumed that the recorded time by this practice is as likely to be too long as short and that while one patron would profit another would suffer, yet the net result in revenue to the company would average about right. In practice, however, this is not found to be the case. The same human frailty which permits operators in a telephone exchange to grow careless and inattentive to their duties will also prompt them, when compelled during a rush period to estimate the time, to make such estimate in a manner to avoid complaint from the patron, the result being that more than 90 per cent. of the errors which occur in timing toll messages are at the expense of the company.

It should not be concluded from these statements that employees in telephone exchanges are thought to be more careless

FIG. 8.

or more liable to errors than others—quite the contrary—it is believed that the high degree of efficiency known to exist in the telephone service in the United States could not be reached but by the employment of operators above the average of intelligence and devotion to duty. It is merely the purpose to

emphasize the statement that no amount of discipline, however rigid, will entirely eliminate the errors due to imperfect human nature, which I shall call the personal errors.

2d. Clocks having visible hour, minute and second hands, when used for timing toll messages, permit recording fractional parts

FIG. 9.

of a minute more readily and more accurately than the clock without second hand, though they are liable to the same errors of vision if improperly placed, and do not remove the personal errors. Indeed the use of the second hand adds to the labor of the operator. She is required to read the clock dial with more care and attention at each connection and disconnection, and to write upon the check the seconds shown upon the clock dial as well as the hour and minute.

In an exchange where clocks with second hands were substituted for the plainer variety, it was found impossible for the operators to handle as much business as formerly. They had been managing eight trunk lines each; and in attempting to record on the toll checks the minutes and seconds, they soon fell behind in their records so far and became so hopelessly entangled that the effort had to be abandoned. Subsequently, a different distribution of trunks was made, each operator handling six, and a test of one hundred connections made with the following result, viz.: Eight records showed errors of more than one minute each; nine showed errors between thirty and sixty seconds each; and eighty-three records were within thirty seconds of the time taken by the inspectors with stop watches. When the operators were given five trunks each, the errors shown were as follows, viz.: More than one minute, five connections; from thirty to sixty seconds, eight connections; less than thirty seconds, eighty-seven connections.

When the operator's load was reduced to four trunks each, the result was: Errors of more than one minute each, four; from thirty to sixty seconds, two; within thirty seconds, ninety-four. In each of these three cases, expert operators were employed, and they had full knowledge of the progress of the tests.

The stop watches used were set so as to agree exactly with the clocks, they having been previously regulated so as to run practically in unison. It was believed, therefore, that a comparison of the time recorded upon the checks with that obtained by listening in would show whether the errors were due to reading the clock dial wrong or to lack of supervision. For

example, when, upon comparison, it was found that the operator's time for connection and disconnection agreed with the time obtained by listening in as to seconds, but varied as to minutes, the error was thought to be due to incorrect reading of the clock dial. Thus, in the test made on six trunks, of the eight errors exceeding one minute each, five were credited to lack of supervision and three were charged to the account of vision.

3d. Clocks showing figures through openings in the dial have been employed in telephone exchanges for timing messages for the reason that errors due to an oblique view of the dial do not occur, and all operators in the exchange (if it be one of moderate size) may see the time alike at the same moment on the dial of a single clock.

The most practicable form of construction employed in such clocks is that which drives forward in a sudden jump the figures representing the minute at the end of each minute, and the figures representing the hour at the end of each hour. One minute is thus exposed to view continuously until the following minute is completed. See Fig. 3. It will be obvious that

but placed in a horizontal plane at the top of the instrument. The pointers which indicate the hours and minute are made to rotate in the centre of the dial, and in order that both pointers and dial may be printed at the same time, their tops or printing surfaces are in the same plane. Since these pointers, obviously, cannot cross each other in their revolutions, as do the hands on the visible dial of a clock, and still remain in the same plane for printing purposes, it is usual to make the hour pointer in the form of a triangle, and it is placed within the circle of figures with its apex pointing outward and adjacent to the figures. The minute pointer is usually made in the form of an arrow; and since it travels faster, making twelve revolutions to one of the hour pointer, it must pass it as many times, and to accomplish this it is placed in the centre of the circle and is made short, that its point may pass the heel of the hour pointer. Thus, in a printed impression made by a time stamp of this type, the point of the minute indicator is a long distance from the divisions or minute marks of the circle, as shown in the diagram. See Fig. 4.

As will appear upon examination of this diagram, it is diffi-

FIG. 13.

fractional parts of a minute cannot be recorded by the use of a clock of this style. Unless, therefore, the operator has her eyes fixed continually upon the clock face, a possible error of fifty-nine seconds may occur in every record. While, therefore, one variety of error has been eliminated by the employment of this style of a clock a new form of error quite as dangerous has been introduced, and the personal equation remains the same.

4th. Time Stamps when employed in telephone exchanges for timing toll messages mark a decided step in advance of the visible clock dial, in that a printed record is made upon the toll check by the stamp without the intervention of pencil or vision. Thus, nominally, errors due to both memory and vision are eliminated. I shall consider what happens in practice.

At the present writing, time stamps available for this purpose (in the market) are of a great variety of construction, ranging in quality from good to indifferent, bad to execrable. All are constructed to print the hour of the day, some shift automatically from a. m. to p. m.; others require these letters to be shifted by the operator when the hours of 12 noon and midnight are passed. Some styles record also the day of the month and year, shifting automatically; others require such mechanism to be set daily.

A common form of construction has the figures of the printing dial arranged in a circle similar to those of a clock dial,

cult to determine at a glance which minute mark on the circle is indicated by the pointed, unless one place a straight edge across the centre of dial. An error of one or more minutes might thus be made in reading a record made by this style of time stamp. Moreover, in instruments of this class, the gear wheels which actuate the pointers have considerable play (back lash), and when the printing platen is brought down upon the dial by a blow from the fist or palm of the hand, the pointers are liable to jump forward or backward sufficiently to cause an error in the printed record of from two to three minutes, thus rendering this type of time stamp wholly unfit for accurate records.

For the purpose of eliminating the errors due to the great distance between minute pointer and minute divisions, another form of time stamp is made with a single stationary pointer and two revolving dials, one having figures to represent the hours, the other figures representing minutes, the latter revolving outside and adjacent to the pointer, as indicated in Fig. 5. In this construction, however, the same back-lash occurs between the wheels which actuate the dials and the same errors occur from this cause.

In another type of time stamp, figures to indicate hours and minutes are arranged upon the periphery of wheels, which are placed in a vertical position under the printing platen, those

figures only which indicate the time being printed. Other wheels indicating date are often added. A printed impression from this style of construction is shown in Fig. 6. This is the most easily read of any time stamp record, being clear and distinct. The printing wheels in this construction, however, are actuated by a step by step mechanism, the minute wheel jumping forward at the end of each minute. It is, therefore, possible for each record to show an error of fifty-nine seconds, in the same manner as do clocks considered under our third heading, which show figures through a hole in the dial. In timing toll messages with time stamps, it is necessary to make a printed record upon the toll check when the connection is made, and another at the time of disconnection; then either the operator or some other person charged with such duty must subtract the one from the other in order to arrive at the elapsed time, upon which the charge is based. Herein an opportunity is presented for the personal error to enter, and it will appear that the time stamp is not the ideal device for timing toll messages. The available time stamps of the present are all, I believe, with one or two unimportant exceptions, operated by striking a blow of considerable force. Those familiar with the operation of telephone exchanges need not be reminded that the noise and jar consequent upon the pounding of several time stamps on a switchboard would soon become an intolerable nuisance, not to mention the bruising of the operator's hands. The necessity for such pounding in the operation of time stamps is moreover an inherent weakness in all instruments so constructed, directly affecting the time-keeping mechanism, making frequent repairs imperative and shortening the life of the instrument. The several attempts to remedy this defect by separating the timing from the printing mechanism and connecting the two by rods, pneumatic or electrical devices, have been only partially successful.

5th. Stop Watches, when employed in timing toll messages, makes possible great accuracy, as, if the operator has little other work to engage her attention each message may be timed to the second; and, moreover, it is not necessary to subtract the commencing from the finishing time, the elapsed time being indicated by the position of the pointers upon the watch dial at the moment they are stopped, by pressing the button when the conversation is completed. Thus the possibility of errors in subtraction are eliminated and if the visible record of time consumed in the conversation is at once written down upon the toll check before the "push piece" or button of watch is pressed to restore the pointers to the zero mark, errors chargeable to the memory do not enter into the record. In a busy exchange this is not always possible, especially where prompt service is rendered, and the watch is often started off upon the measurement of another message before the elapsed time of the first one is written down. Thus, in practice, the memory of the operator is made a factor even where the message is at first accurately timed.

As but one message can be timed by a stop watch at once, it is obvious that several watches must be used by each operator, at least one for each trunk line, and the watches should be arranged in a rack and numbered to correspond with the trunks, as indicated in Fig. 7. Stop watches suitable for this purpose should be provided with both second and minute pointers, which return to the zero mark on the dial by pressing the button or winding crown. It is not essential that they should also show the time of day. Indeed the additional pointers on the dial necessary for such purpose are likely to be confusing to the operator and afford occasion for an incorrect reading.

Accurate and reliable stop watches may be procured at a cost of from \$15.00 to \$25.00 each. Many cheaper varieties are in the market, some of them selling as low as \$3.50 to \$5.00 each, but these are so poorly constructed and so roughly finished as to be wholly unreliable and absolutely worthless for the purpose for which they are designed.

I have never seen stop watches of the better class used in telephone exchanges, probably because of the considerable expense involved in equipping a switchboard with the requisite number, viz.: One watch for each trunk line.

In several exchanges watches of the cheaper varieties were found, but they were reported by the managers as "very unsatisfactory," out of order and in the hands of the repairer a great part of the time," and "a constant source of trouble and annoyance." In other places I learned that stop watches had

once been used for timing toll messages, but their use had been discontinued for similar reasons.

6th. The Calculagraph is an instrument which makes a printed record of elapsed time, i. e., it mechanically subtracts the time of connection from the time of disconnection and prints upon the ticket the actual time which elapsed during the interval; the operator being required only to insert a ticket in the slot and pull a lever at the commencement and repeat this operation at the finish. For use in telephone exchanges the calculagraph is so constructed as to make such records of elapsed time in minutes and quarter-minutes. For other purposes it is arranged to record elapsed time in hours and minutes. A still further modification of this instrument multiplies the elapsed time by the rate of charge per minute or hour and records the actual amount charged for the service rendered. Such record may be made in dollars and cents or in the denominations of money employed in the several foreign countries. This latter form of the calculagraph is rarely used in telephone exchanges, though it may be employed where a flat rate prevails.

The elapsed time record made by a calculagraph adapted for telephone service is shown in Fig. 8. The left hand dial shows twenty divisions and five figures, the four spaces between each two adjacent figures indicate quarter-minutes. A movement of the pointer on this dial from one space to the next indicates one-quarter of a minute, and a complete revolution five minutes. The right hand dial is divided into twelve spaces, each space indicating five minutes. The pointer on this dial makes a complete revolution in sixty minutes, and passes from one space to the next during the time of an entire revolution by the left hand pointer. Thus, the even periods of five minutes each are read on the right hand dial, and fractional parts of such periods down to quarter minutes are read on the left hand dial. This arrangement of dials is exactly suited for recording toll messages where the charges are based on periods of five minutes each. A similar arrangement of dials may be employed to suit the practice of basing charges for such service on periods of three minutes each.

When a record of the time of day is required in addition to the elapsed time, the calculagraph is provided with a supplementary dial and pointers which make a record as shown at the extreme right in Fig. 9. The triangular-shaped pointer indicating the hour is made to revolve outside the circle of figures and the minute-pointer in the centre is extended so that its point is adjacent to the minute divisions, thus eliminating the objectionable features of the time stamp dial shown in Fig. 4. The time-of-day dial on the calculagraph is printed by giving a backward movement to one of the levers which operate the elapsed time dials.

The complete calculagraph is also provided with visible dial and hands, and is shown in a portable case in Fig. 10. In this form it may be used on a desk or table.

In Fig. 11 it is shown mounted on a stand or pedestal. In Fig. 12 it is shown in a case adapted to be sunk in switchboard shelf with its top flush. Fig. 13 shows one corner of a telephone exchange with calculagraphs fitted into the switchboards.

It will be apparent that what I have heretofore denominated as the error of vision, conspicuously present in the use of a clock with visible dials and pointers, is absent when the calculagraph is employed to measure toll messages. Errors made in subtracting the time of connection from the time of disconnection are also eliminated, as such calculation is made mechanically by this instrument. Errors of the memory and those due to the practice of estimating the time some minutes after the transaction is closed, need not occur in the use of the calculagraph, as the operator may perform the simple operation of pulling a lever to complete a record while her attention is devoted to the needs of some other patron.

The calculagraph goes two steps farther than the stop watch. First, in that while the latter shows, visible on its dial, the elapsed time, the former prints the elapsed time on a ticket; and, second, while the watch can show but a single record of elapsed time at once, the number of such records which may be made by the calculagraph during a single period is limited only to the number of times it is possible for an operator to insert a ticket and pull the lever. It is, therefore, necessary for each operator to use but a single instrument instead of a separate one for each trunk line. Indeed, in many exchanges, two adjacent operators use the same calculagraph, which is placed in the switchboard between them.

The calculagraph is noiseless; its operation being effected by pulling levers and is not accompanied by that pounding, bruising of the hand and jarring of the mechanism mentioned in connection with the time stamps. Its platen is not jammed down by a sudden violent stroke upon the dials, causing them to jump backward and forward; but the dials are moved upward by a steady, even pressure against the printing platen while their rotation continues steadily forward, the back-lash being taken up by a retaining spring, the time-keeping mechanism remaining undisturbed.

Tests were made by listening in in 20 exchanges where the calculagraph was employed, 500 connections being tested in each, making a total of 10,000 messages tested, with results showing an average error of less than four seconds per message.

No figures are available indicating what errors occurred in timing messages in those exchanges before the calculagraph was introduced, nor the amounts added to the revenue of the companies by the elimination of such errors; but the managers freely admit a very decided improvement in the service, with a feeling of assurance that no injustice results to any one. It is not claimed by the manufacturers of the calculagraph that it is entirely automatic. It will not pull its own levers, the tickets must be inserted in the slot and against the guides, and its use will not permit dispensing with the service of operators; but it does unquestionably relieve the operators of considerable mental effort, and the simple mechanical operation of pulling a lever to complete one record may be performed while the operator is engaged in helping out some other patron who has encountered difficulties in the service, and greater efficiency is thereby attained. In several of the larger exchanges where the calculagraph has been introduced for timing toll messages, the services of a clerk formerly employed to calculate the elapsed time upon tickets and check up the work of operators has been dispensed with, and the salaries of such clerks saved to the companies; the records left by the calculagraph upon the tickets being considered more accurate than the clerks could possibly make.

Moreover, the use of the calculagraph has made it possible to discontinue the practice of timing toll messages at both ends of the line; one mechanical record of the time of day and the elapsed time made by the sending operator being considered entirely sufficient for all business purposes.

The former practice of timing at both ends could be justified only on the ground that errors were known to be frequent, and the theory that prevailed was, that "both sending and receiving operators were not likely to make the same error at the same time; therefore, a compromise figure taken from some point between the two records must be approximately correct."

When the receiving operator is relieved entirely of the necessity of making out tickets with names of calling and responding parties, time of connection and disconnection, elapsed time and other data, it will be obvious that her efficiency in the other duties of operating should be enormously increased.

A saving is also effected in the cost of the duplicate tickets and the clerical labor involved in comparing and compiling such tickets.

But the item of greatest value to the company saved in this reform in operating methods, consists in relieving valuable trunk lines of such interruptions to profitable business as occur when sending and receiving operators hold up a line while they discuss the question of the correctness of the records of elapsed time each has made on the previous message, and endeavor to agree upon some satisfactory compromise figure, or try to "force a balance."

During the past two years calculagraphs have been quite generally introduced into the exchanges of licensees of the American Bell Telephone Company where any considerable amount of toll business is handled. They are also to some extent used by large business houses whose transactions over long distance telephone lines are of considerable magnitude, for the purpose of checking up and verifying the items of their bills for telephone toll service.

If any reader of *The Electrical Engineer* may be charged with the management of a telephone exchange, and has heretofore rested secure in the belief that "any method is good enough," shall be persuaded to investigate what happens in the timing of his toll messages, he may be assured of a surprise in learning what the errors cost his company in revenue, and the writer shall feel that ink and paper have not been wasted.

A Great Advance in Fire Alarm Telegraph Protection.¹

BY J. W. AYDON,

Supt. Fire Telegraph, Wilmington, Del.

I DESIRE to present to the convention a brief description of the most important and recent advance in methods of fire alarm protection, which will make the outbreak of a fire and the sounding of the alarm through the municipal system practically simultaneous. Nothing further than this preliminary statement is necessary to command the attention of this convention, made up as it is of men whose experience teaches them that the smallest space of time lost between the discovery of a fire and the giving of an alarm may often result in serious loss of life and property and add immensely to the dangers and difficulties which fire departments have to contend with in the performance of their duty.

I refer particularly to a combination with the well-known auxiliary fire alarm system of a so-called "Multiphase" cable, which combination makes the auxiliary system automatic as well as manual.

The auxiliary system proper was an immense step forward in this vital matter of minimizing the time between the discovery of a fire and the giving of an alarm, and its record throughout the country for the past six years has been a most excellent one. During this time it has been in quite extensive use in many of the large cities of the United States, and in those places has been a considerable factor in reducing the fire losses, and has been a material aid to the fire departments.

In the city of Wilmington it has rendered exceptional service to property holders and to the department, and has been the means of preventing several serious fires by enabling the fire department to reach the scene of the fire some minutes sooner than would have been the case otherwise.

The auxiliary system, in effect, brought the nearest public fire alarm box into the interiors of buildings, and placed it at any desired number of points, by providing a series of small auxiliary boxes, from any one of which the street box could be instantly operated by the pulling down of a lever contained in each auxiliary box. But the system, being purely manual, was not effective when the protected premises were vacant; and it was to cover this point that the method of rendering the auxiliary system automatic, as well as manual, was perfected.

The great value of an automatic connection with municipal fire departments has been long recognized, and for many years received the hearty co-operation and encouragement of insurance underwriters and fire department officials; and under the fostering influence of these interests it has rendered, and is rendering, most valuable service.

The growth of the automatic system, however, has necessarily been confined to the larger cities, for the reason that it is necessary to maintain the system in connection with its own central office, through which alarms of fire have to be transmitted to the fire department. The expense of wiring and the cost of maintaining a central office equipment is so great that the business cannot be made a commercial success, except in large cities where the volume of business is considerable.

For smaller cities, where the amount of property to be protected is not so large, but relatively equally valuable, the automatic system is not available; but the record of this system covering a period of many years has exclusively proven that a reliable automatic system, available wherever there is a fire department, would be of vast importance.

The successful operation of an automatic system in smaller places is now for the first time in the history of fire telegraphy possible. It has never been a matter of electrical or mechanical difficulty to connect ordinary thermostats into an auxiliary system so that an excess of heat would automatically operate the street box, but the danger of unnecessary alarms has prohibited this.

The recent invention of the "Multiphase" cable, referred to above, has been adapted for use in connection with the auxiliary system, so that it becomes automatic, as well as manual, without the sacrifice of any of the peculiar features of safety from false alarms, which is the foundation of the willingness of fire departments to allow its use in connection with street boxes.

This "Multiphase" cable is of peculiar construction, as will be

¹Paper read at Municipal Electricians' Convention, Elmira, N. Y.

noted from the drawings which I have for your examination. Briefly, it consists of a copper conductor having a fusible metal covering, with insulated material over it, around which is wound a series of small copper wires, the whole being again protected by a slow-burning insulation. This cable is wired into the auxiliary system in the place of the ordinary wire heretofore used, and in connection therewith is run a single wire composed of fusible wire only, and protected with a free-burning insulation.

An automatic-auxiliary equipment would, therefore, consist of the desired number of auxiliary boxes, distributed throughout a building at convenient locations, connected through the usual testing apparatus, with the nearest street fire alarm box. The interior wiring of the equipment would be of this "Multiphase" cable described, and the single fusible wire mentioned, the cable wire being run parallel to each other.

As fires do not start upon the ceilings of rooms (where the ordinary thermostats are placed), the automatic wires referred to would be run around base-boards, back of benches, through closets, under staircases, etc.—in fact, so as to cover every danger point where a fire would be likely to start. These danger points can be scientifically located for each class of risk, by a reference to insurance tables giving the accumulated experience of all the insurance companies for a period of years, as well as by individual judgment in each case.

It will therefore be seen that such an equipment would provide a number of auxiliary stations, which, when manually operated, would instantly get the street box in motion, thereby giving the alarm to the fire department; and would also provide for the covering of all danger points in the building by the automatic cable as indicated.

There is no necessity of describing the operation of the auxiliary system proper—i. e., when operated manually; so we will pass to the working of the "Multiphase" cable when it comes in contact with actual flame.

First, however, let me call the attention of the convention to the fact that it takes actual flame, or a temperature of 360 degrees without flame, to cause this wire to send in an alarm, and this, therefore, prevents false alarms from an overheating of a building, which might not necessarily be dangerous.

This failure to act until the flame comes in contact with the wire or until a temperature of 360 degrees is reached, does not imply that the wire will not give the alarm for an actual fire as quickly as a thermostatic equipment would do; on the contrary, it would doubtless, in most instances, give it quicker, for the reason that every fraction of an inch of the wiring of an auxiliary system would be an alarm-giving point, located where the fire would probably start, instead of being away up on the ceiling, perhaps many feet away from the fire.

The fact that this cable required flame, or a temperature of 360 degrees to operate it, insures it against any liability to false alarms, for conditions producing a temperature at which thermostats act unnecessarily, produce no effect upon it.

Returning now to the operation of the wiring of an auxiliary system equipped with the "Multiphase" cable, under the influence of flame, or 360 degrees of heat; the single fusible wire melts open, and the fusible metal covering of the inner wire in the cable, melts, and forcing its way through the insulation, makes a solid soldered connection with the series of copper wires described.

This action of the wire produces a condition in the auxiliary system, exactly the same as that brought about by the manual pulling of one of the auxiliary boxes, and the alarm through the street box is the immediate result.

This combined system, like the auxiliary system proper, is at all times under automatic test, so that any line or battery disarrangement will be instantly made known. This system combines all of the advantages of an automatic system with all those of the auxiliary system, without any of the disadvantages of the former. It is available wherever there is a street box, in a large city, or small town.

To sum up briefly, the automatic-auxiliary system enables the instant and manual sending of an alarm of fire, and also provides that every fractional part of an inch of its wiring shall be an untiring watchman ready at all times to instantly give the alarm when dread fire makes its appearance.

I think the convention will agree with me that making the fire send in its own alarm is a notable advance in the business to which we are devoting our lives.

Congress Fixes Washington Telephone Rates.

At Washington, on August 4, Judge Hagner, in the District of Columbia Supreme Court, rendered a decision against the Chesapeake and Potomac Telephone Co., and granted an order restraining them from removing instruments from subscribers who refuse to pay more than \$50 per year rental. Congress enacted a law limiting the charges to \$50 per year for each instrument in the District of Columbia. Several subscribers in Washington refused to pay more, and the telephone company attempted to remove the instruments. James F. Manning & Co. commenced legal proceedings to restrain the telephone company from such action. The latter alleged that the act referred only to Government service, and that as otherwise applied it was unconstitutional. Judge Hagner overruled all of the company's objections and granted a temporary restraining order. The telephone company has appealed.

Telephones in Cape Colony.

Consul General Stowe writes from Cape Town, April 25, 1898: The telephone service of Cape Colony is under the control of the colonial government. On the 9th of April, 1898, there were 1,535 instruments in use, and the revenue for 1897 amounted to \$66,137.22. There are 869 miles of wire and 780 subscribers. Seven exchanges in the colony work on the single-wire system, but arrangements are now being made to have all lines duplicated, and in future no exchange will be established except on the metallic-circuit system.

In the course of the next few months the underground cable system in Cape Town will be completed and exchanges established in the suburbs.

Independent Telephony in Michigan.

A special dispatch of August 4 from Grand Rapids, Mich., says: At the annual meeting of the Independent Telephone Association of Michigan, held in this city, J. B. Ware, Grand Rapids, was elected president; Alex. McLeod, Detroit, secretary, and W. H. Tilden, St. John's, treasurer. About 500 Michigan towns now have independent telephone exchanges or connections, and they are divided into three groups. This city is the centre of the largest group, with 300 towns reached. Detroit has about 150, and Saginaw 50. The Detroit and Grand Rapids systems have just been connected by way of Lansing, and the Saginaw system will connect with the other two before the close of the season. It is estimated about 16,000 instruments are in use in the State and this number is rapidly increasing.

Independent Toll Line Telephony in Iowa.

At the meeting of the Iowa Association of Independent Toll Line Telephone Companies on August 11, at Des Moines, the following schedule of toll rates was adopted for a single message:

	Cents.
20 miles or under.....	.20
20 to 30 miles.....	.25

Above 75 miles, five-eighths of 1 cent per mile.

This schedule takes the place of the schedule of rates according to counties through which messages passed. The old percentage of division of receipts was retained. It provides that where a message goes over two lines the originating line gets 60 per cent. of the receipts and the other company 40; in case of three companies, the originating line gets 50 per cent. and the other two 25 each, and in case of four companies, the originating company gets 40 per cent. and the other three 30 each.

WESTERN TELEPHONE CONSTRUCTION CO. has issued a huge colored broadsheet full of very useful and interesting information in regard to features of exchange and toll line equipment. It is well illustrated by cuts of apparatus and diagrams, and is well worth study.

THE FRENCH CABLE CO. has been celebrating the opening of its new cable by messages of kindness between Presidents McKinley and Faure.

[Entered as second-class matter at the New York Post Office, April 3, 1882.]

Vol. XXVI. NEW YORK, AUGUST 25, 1898. No. 538.

Moribund Manhattan.

AT a time when nearly every railroad property in the country is either increasing its dividend rate or its surplus, or is getting upon a dividend basis, the Manhattan Elevated of New York distinguishes itself by losing traffic steadily in the biggest city in the Union and in a centre where travel is growing at a tremendous pace. It now has piled up a floating debt of over \$1,000,000, it is not earning its 4 per cent. dividend, and each report of traffic goes from bad to worse. The last quarterly report showed a deficit of \$16,000 as compared with a surplus of \$89,000 for the corresponding period of 1897. We hesitate to use the word "moribund," in regard to the splendid Manhattan property, but it is difficult to find one that is more appropriate for such a state of affairs.

The great question is: Can the Manhattan Railroad be revived? We believe it can be and that electricity will do it. Such an opinion might naturally be expected from an electrical journal, but as we recommended the change, by way of a precautionary measure, before its fortunes went to the bad, we feel no hesitancy in urging it strongly again, especially as those in authority hesitate so long about this vital matter. It might be said that, electricity or not, the competition of the Metropolitan Traction surface cars is responsible for the whole trouble and that their advantages cannot be offset, especially as the system is still extending and is sapping the patronage of the Manhattan at a growing number of points. In other words, it is claimed that the elevated roads have lost their short distance travel and cannot regain it.

This is a view of the situation we do not take; and as the Metropolitan is emphatically an electrical system and has achieved its notable success by becoming so, we might urge the argument that conditions would be equalized by the Manhattan following suit. The Elevated had once to compete with the horse cars and cable cars, and held its own against them, even on the short travel, but now that the surface cars have dispensed with horses and have adopted mechanical traction, becoming cleaner, neater and more brilliant, they have jumped into great popularity. Yet even for short distances they do not strike us as always surpassing the elevated cars in speed between many given points. We have tried it repeatedly, but have gone back to the Elevated if in a hurry. Otherwise, the surface cars get our preference; and, besides, there are no stairs to climb and there are no long waits.

Now let us see what the Elevated could do. First of all, it could adopt electricity. In fact, it must do so, or die, i. e., become bankrupt, living then only on through travel, limited chiefly to expresses. In making this change to electricity the Elevated will get rid of its villainous coal dust and other incidental annoyances. You can rarely go up and down town by

the road without getting its dust in your eyes or over your clothes, and if you walk underneath it, you have to dodge cinders and oil and drippings and dust all the time. It is distinctly barbaric and antiquated. Then, in changing to electricity, the cars can be better lighted and better heated, while in summer open cars could be run, on regular schedule, something that is now impossible with steam for locomotion. Last of all, elevators could be put in at all the stations with long flights of stairs; and there are few without such flights, turning away many delicate passengers daily, because of the exertion they necessitate.

There are some apologists for the Manhattan Company in its long delay, and among them high authorities. For example, Col. H. G. Prout, editor of the "Railroad Gazette," in a recent able and thoughtful article said:

"Whether or not electricity would save anything in cost of operation in this special case is a matter of debate among experts. The steam locomotives now used on the Manhattan Elevated are efficient machines, and, taken all in all, the elevated railroads of New York give the people a service which, in the combination of the magnitude of the traffic, the safety with which it is carried, the speed, the regularity, the comfort and the economy, is unparalleled in the history of transportation; it is probable no other instance can be found in which these elements are combined on such a scale. But, further, the service is possibly the most intense in the world, and an interruption causes inconvenience to thousands of people. But with the steam locomotive each train is a self-contained unit, and an accident to that train does not necessarily interrupt the traffic over the whole line or interrupt it for a considerable time, but with electric working the whole system is on one string. A failure in the power house or in the conductors stops everything. In practice this difficulty is not as serious as it is in theory, but the danger is present, and the prudent engineer is bound to think of it when he decides between steam and electricity."

This seems to us praise too warm for a service that in reality is dying of dry rot. Conceding all that is put forward to be true, there is left the great fact that people have found and go on finding something better in the Metropolitan Traction service. Besides, there is implied a condemnation of every modern trolley or cable system, for they all depend on power houses instead of individual self-contained motors. We have yet to gather from our prolonged observation that they are more liable to delay, stoppage and breakdown than the Elevated has been; although they do not enjoy the long sidings, switches and turnouts which enable the Elevated, unhampered by street travel, to lift a blockade, as it has often to do. Without its "third track" the Elevated would, we fear, from what we see, be "tied up" every day of the week, in spite of its self-contained motors; whereas it is likely that if one power house were shut down for any cause, the Metropolitan Traction Company could throw current in from others, over alternative conductors, at the desired points. Why it should be supposed that the Manhattan Elevated must depend on one, or even on two, power plants we do not exactly understand. To say the least, that is not the existing practice on electric surface roads of any magnitude.

If we figure it aright, the Manhattan system has to pay fixed charges on about \$40,000,000 and has \$30,000,000 of stock. Its rate of dividend was reduced in April, 1897, to 4 per cent., but now it is not earning that; and soon it may not be able to meet its fixed obligations. It is no wonder that the stock has fallen below par, even in these days of widening prosperity, in an expanding city, when the Metropolitan Traction cannot get cars enough for its passengers. The cost of introducing electricity is put at about \$8,000,000. Let us call it \$10,000,000. Four per cent. on that is \$400,000, which means 8,000,000 fares a year, or about 22,000 a day. It does not seem to require much boldness on our part to predict that with an electrical equipment permitting it to run trains under greater acceleration and shorter headway, and yet in units from one car up, the road would at once carry not merely 22,000 people more every day but 100,000.

The Manhattan road has been an inestimable boon to the citizens of New York. It still remains so, but its usefulness is lessening as the city and municipal needs grow, and a change must come. That change may perhaps be found in absorption by the Metropolitan, whose vigor, alertness and progressiveness have been in curious antithesis to the sad, Spanish apathy and indifference of the Manhattan management. We do not wish to condemn unfairly, but the Manhattan figures are stronger than anything its critics may indite.

When Jackie Comes Sailing Home.

IT was indeed a glorious week, the one just passed, one of the proudest episodes in American history. It was a week of welcome, days of thrilling excitement and paying of homage to those who on land and sea alike have won glorious and decisive victories. Our soldiers, brave and true, have returned to their native land, and, worn out by weeks of privation, exposure to the elements and an unfavorable climate, have been sent to healthful camping grounds for recuperation and treatment. Our naval heroes and our "Jackies" who in so short a space of time gave to Spain the largest submarine navy in the world, have again touched our shores amid a royal, American welcome. We have learned to love those brave and fearless boys and are proud of their triumphs and victories.

But apart from the pride which these events have naturally awakened, the war just closed has taught us more serious lessons, namely, those relating to the science of war, such as the armament of troops and vessels and the handling of machinery on board a man-of-war. It is true that the entire scheme and system of our electrical installations on shipboard has been, from the nature of the case, progressive, but we may confidently say, they have shown a steady improvement in details and efficiency. Electricity is being used for every conceivable purpose, so as to minimize as much as possible the present objectionable heat of long lines of steam piping, the annoying leaks of hydraulic apparatus and the excessive weight of pneumatic appliances. To this may be added the fact that a break in a steam or hydraulic pipe could easily drive every one from the compartment. Perhaps the greatest argument, however, in favor of electricity is the ready change from electrical to hand control in emergency, and the facility of maintaining and repairing the leads. As a proof of the perfect control of electrical power as applied to turrets, we may mention the instance at a trial on the Brooklyn at Cramp's shipyard, when the turret was successfully started and stopped thirty-seven times in a peripheral distance of one inch in the same direction, a result which challenges competition.

These and other, now apparently indispensable apparatus, and the generating plants, have been brought to a high state of efficiency through the research and patient insistence of those who worked out its early details. What we need most now is care and skill in manipulation. Lieutenant B. T. Walling, U. S. N., in a lecture delivered before the U. S. Naval War College, tells us that "continuity of service and endurance of our plants is now suffering from lack of interest and apathy on the part of officers." This criticism, made before the war, has by no means been borne out by the successful maneuvering of our ships and guns during the critical moments of warfare and in the midst of battles and bombardments. But be this as it may, the apparatus on board our men-of-war must certainly have suffered from the severe duties to which it has recently been subjected and, like our wounded heroes, it needs care and treatment. Machines, like the sailors, are only serviceable when in sound condition, and are liable to get ill and unfit for duty for lack of attention of from overexertion. Now is the time to administer the medicine and correct faults of early work which must have been brought to light by the exacting requirements of actual service. Many of our ships still have antiquated and inefficient generating sets on board which should be substituted at once by the most modern and improved types. More perhaps than in any other portion of the ship, cleanliness should be insisted upon in the engine and dynamo rooms, and all leaks into them be carefully sealed, as lack of cleanliness and presence of salt water are the inveterate enemies of electricity on board ship. Lieutenant Walling points this out as one of the many diseases of electrical installations in the navy, of which he appears to have made a careful study. He tells us of the practice of putting paint on the end conductors of armatures for appearance sake, a material more baneful to armature coils than oil and dirt, not only on account of the deteriorating effect of its oil on rubber, but through the non-conducting layer established. Once applied it cannot be removed, and when dirty it is cleaned by another coat of paint, producing more resistance to radiation. Usually the armature burns, he says, occur at these very end conductors.

He also points to the unnecessary vibration and noise due to the running machinery, all of which can be easily abolished by proper support and location and the adjustment and smooth running of all parts and fittings. Many of our switchboards,

says Lieutenant Walling, have been insufficiently supported, thereby bringing a stress upon and loosening the circuit connections of the panels. He further points out the inadvisability of using marble for switchboards and porcelain for insulating knobs and other purposes on account of their liability to break, and suggests the use of micanite, properly framed by an insulating material such as a vulcanized rubber composition. He decries the value of lead covered wire, on account of the difficulty of its repair, the manipulation consequent upon its weight and the almost certain breakage at bends and angles. It has fallen short of the anticipated advantages claimed for its use in heated locations and is peculiarly susceptible to electrolytic action.

It appears that now, when most of our ships will be put in dry dock, is the time to remedy these and other shortcomings which are said to exist in our naval electrical installations, and make such changes as have suggested themselves during the recent engagements. It is but another instance of preparing for war in time of peace.

Scaling Down and Scaling Up.

ONE of the most interesting passages in Reid's history of the telegraph in America is that in which is described the doubling up of the capital of the Western Union Telegraph Co. from \$11,000,000 to \$22,000,000 in the flush times of the Civil War period. The stock was being quoted at 225, and so the change was felt justifiable. "It seemed a splendid achievement thus, by a breath, to create \$11,000,000" by means of a stock dividend of 100 per cent. This increase was followed by others, due to consolidations, and \$25,000,000 soon became \$41,000,000. But the rub came when dividends had to be paid on this capitalization, and then the burden was felt in its true weight.

To-day the Western Union earns and pays its dividends on \$100,000,000, a capitalization which seems but fairly to represent the intrinsic worth of the property. We venture therefore to hope that in due time the General Electric Co. may find its history, which has been parallel in many respects though not in all, following the same upward curve. Last week the General Electric Co., instead of scaling up, followed the reverse and less pleasant practice of scaling down, and "at a breath" reduced its capital to \$20,827,000, wiping out about \$20,000,000. It is but a few years ago that upon the union of the Edison and Thomson-Houston companies all this water was injected into the corporation that has now been squeezed out. At that time in spite of the general enthusiasm, some shrewd observers doubted the company's ability to earn dividends, but things looked rosy until the panic of 1893 came, and with it the smash. Stock then selling at about 115 has since sold at 30. Such a drop was inevitable, for in July the company owed \$1,488,000 accumulated dividends on its preferred stock, and had paid nothing on its common stock since August, 1893.

The present scaling down includes \$4,000,000 knocked off the patent account, a reduction which can only be commended and which, as we have often urged, ought to have been made long ago. As to the general reduction, it looks like serious injustice to the preferred stockholders; but all depends on the point of view. When a ship is badly swamped, anything goes overboard that will lighten her. The main thing is to get her righted and keep her buoyant. This we take to be the aim of the directors of the company, many of them men of highest standing and reputation. There may have been gambling in the common stock, which apparently benefits at the expense of the preferred, but the dealings in the stock for months past give little sign of it. If there has been a "play" of that kind, its evidences are to be looked for rather in the future.

Now that the water has been squeezed out of this great property, we trust it will be able to earn and pay steady dividends. That will be one of the best things that could happen to the growing industry of electric light and power. For the General Electric Co. to sink out of existence with all that it represents of genius, effort, invention, investment and opportunity, would be one of the worst disasters to the general electrical industry we can imagine. If any word of ours counts with the management, we would again recommend a conciliatory policy, for whatever present patents may be worth, they will always undergo diminution as the art advances and widens, and no art amplifies more quickly than the electric. If the General Electric is to prosper, and we heartily trust it may, it will do so by making friends, not enemies. Of the latter it has enough already, and they are not enemies by their own choice.

Tesla Circuit Controllers for Obtaining Oscillatory Currents of High Frequency.

ON August 16 a very ingenious and apparently significant group of patents was issued to Mr. Nikola Tesla, comprising several types of current-interrupting devices for obtaining oscillatory currents of very high frequency. Mr. Tesla has called them "electrical circuit controllers" and their use and construction may be understood by the following introductory remarks, taken from the patent specification referring to the class of circuits for which they were designed. We present also several illustrations showing the latest forms developed by Mr. Tesla, whose persistent investigations along the high frequency line entitle him to much praise and credit.

In every form of electrical apparatus involving a means for making and breaking more or less abruptly, a circuit, a waste of energy occurs during the periods of make or break, or both, due to the passage of the current through an arc formed between the receding or approaching terminals or contacts, or, more generally, through a path of high resistance. The tendency of the current to persist after the actual disjunction or to precede the conjunction of the terminals exists in varying degrees in different forms of apparatus, according to the special conditions

FIG. 1.

present. For example, in the case of an ordinary induction coil the tendency to the formation of an arc at the break is, as a rule, the greater, while in certain forms of apparatus in which the discharge of a condenser is utilized this tendency is greatest at the instant immediately preceding the conjunction of the contacts of the circuit-controller which effects the discharge of the condenser.

The loss of energy occasioned by the causes mentioned may be very considerable and is generally such as to greatly restrict the use of the circuit-controller and render impossible a practical and economical conversion of considerable amounts of electrical energy by its means, particularly in cases in which a high frequency of the makes and breaks is required.

Extended experiments and investigation conducted with the aim of discovering a means for avoiding the loss incident to the use of ordinary forms of circuit-controllers have led Mr. Tesla to recognize certain laws governing the waste of energy and making it dependent chiefly on the velocity with which the terminals approach and recede from one another and also more or less on the form of the current-wave. Briefly stated, from both theoretical considerations and practical experiment, it appears that the loss of energy in any device for making and breaking a circuit, other conditions being the same, is inversely

proportional rather to the square than to the first power of the speed or relative velocity of the terminals in approaching and receding from one another in an instance in which the current-curve is not so steep as to materially depart from one which may be represented by a sine function of the time; but such a

FIG. 2.

case seldom obtains in practice. On the contrary, the current-curve resulting from a make and break is generally very steep, and particularly so when, as in Mr. Tesla's system, the circuit-controller effects the charging and discharging of a condenser, and consequently the loss of energy is still more rapidly reduced by increased velocity of approach and separation. The demonstration of these facts and the recognition of the impossibility of attaining the desired results by using ordinary forms of circuit-controllers led Mr. Tesla to invent other means for making and breaking a circuit in which he has utilized a conducting fluid, such as mercury, as the material for one or both of the terminals and devised novel means for effecting a rapidly-intermittent contact between the fluid and a conductor or series of conductors forming the other terminal.

In this apparatus one of the members or terminals is a conducting fluid which is caused to issue from an orifice against a series of spaced conductors in rapid succession. For this purpose the series of conductors, or it may be a single conductor, is moved transversely through the stream or jet of fluid, or the jet is moved so as to impinge upon the conductors, or both jet and conductors are moved. This is preferably accomplished

FIG. 3.

by mounting the conductors and the tube or duct from which the fluid issues concentrically and revolving one or both.

The plan adopted for maintaining the stream or jet of conducting fluid consists in utilizing the same power that actuates or drives the circuit-controller in effecting the necessary rela-

tive movement of its terminals to maintain the proper circulation of the conducting fluid by combining the two mechanisms (the controller and the means for maintaining a circulation of the conducting fluid) in one. This feature is of great practical advantage and may be effected in many ways. A typical arrangement for this purpose is to provide a tube or duct having an orifice at the end directed toward the spaced conductors and its other end in a position to take up a portion of the rapidly-rotating body of conducting fluid, divert it through the duct, and discharge it against the conductors. With this object when a closed receptacle is used a holder for the tube is employed, mounted within the receptacle and concentrically therewith, and this holder, when the receptacle is revolved, is held or influenced by any suitable means, as by magnetic attraction exerted from the outside or otherwise, in such manner as to keep it either in a fixed position or impress upon it a velocity different from that of the rotated fluid.

The general scheme of the system for use with which the circuit-controllers are more especially designed will be under-

FIGS. 4 AND 5.

stood by referring to Fig. 1. In this figure A A represent the terminals of a source of current. A' is a self-induction or choking coil included in one branch of the circuit and permanently connected to one side of a condenser A". The opposite terminal of this condenser is connected to the other terminal of the source through the primary B of a transformer, the secondary B' of which supplies the working circuit containing any suitable translating devices, as B".

The circuit-controller C, which is represented conventionally, operates to make and break a bridge from one terminal of the source to a point between the choking-coil A' and the condenser A", from which it will result that when the circuit is completed through the controller the choking-coil A' is short-circuited and stores energy which is discharged into the condenser when the controller-circuit is broken, to be in turn discharged from the condenser through the primary B when these two are short-circuited by the subsequent completion of the controller-circuit.

Six different constructions of circuit controllers have been patented by Mr. Tesla in this group referred to in the beginning of this article, but we have selected three of them which illustrate fairly well the various types for which patents were granted.

Referring to Fig. 2, the operative portions of the circuit-controlling mechanism are contained in a closed cylindrical recep-

table A, of iron or steel, mounted on a spindle B in a suitable socket or support C to permit it to be freely and rapidly rotated. The socket C is secured to or forms a part of a base or stand D.

As a means of producing the proper rotation of the receptacle A, a field-magnet E is shown, mounted on or secured to the base D, and an armature F, supported by a bracket G from the under side of the receptacle A. The same bracket also carries a series of commutator-segments H, upon which bear brushes I, these parts being arranged to constitute an electromagnetic motor with stationary field and rotating armature. Any other suitable means, however, may be employed to rotate the receptacle and the fluid.

In the spindle B and concentric with its axis is a spindle J in bearings specially constructed to reduce friction in order that the spindle J may be as little as possible influenced by the rotation of the main spindle and receptacle which it carries. A suitable provision is made to oppose or prevent the rotation of the spindle J during the rotation of the receptacle. For this purpose the following has been devised.

The spindle B is held by its bearings at an angle to the vertical, and a weight K is secured eccentrically to the spindle J and tends to hold the spindle always in one position. The inclination of the axes of rotation necessary for this result may be as shown, and should not be greater, for the reason that it is especially advantageous to preserve the spindles and bearings as nearly as practicable vertical on account of lesser friction and easier lubrication.

Attached to the spindle J or weight K is an insulated bracket L, carrying a standard or socket M, in which is mounted on antifriction-bearings a spindle N. Secured to this latter is a plate with radial arms O, from which depend vanes or blades P, with projections Q extending radially from it. A shield or screen R incloses the vanes, except on the side adjacent to the inner periphery of the receptacle A.

A small quantity of a conducting fluid S is placed in the receptacle, and in order to secure a good electrical connection between the vanes P and a terminal on the outside of the receptacle a small mercury-cup T, in metallic contact with the vanes through the bracket L and socket M, is secured to the weight K. A metal stud V, set in an insulated bolt W, projects into the cup T through a packed opening in its cover. One terminal of the circuit-controlling mechanism will thus be any part of the metal receptacle and the other the insulated bolt W. The apparatus may be connected up in circuit by connecting the wires of the circuit to a brush X, bearing on the bolt W, and to a binding-post Y in contact with the base D.

To operate the apparatus, the receptacle is set in rotation, and as its speed increases the mercury or other conducting fluid which it contains is carried by centrifugal force up the sides of the inner wall, over which it spreads in a layer. When this layer rises sufficiently to encounter the projections Q on the blades or vanes P, the latter are set in rapid rotation, and the electrical connection between the terminal of the apparatus is thereby made and broken, it may be, with very great rapidity.

The projections Q are preferably placed at different heights on the vanes P, so as to secure greater certainty of good contact with the mercury film when in rapid rotation.

Fig. 3 is a central vertical cross-section of another type, which involves two salient features of novelty, one that it provides for maintaining in a rotating receptacle a stationary jet or jets which by impinging on a rigid conductor maintain the latter in rotation, thereby securing the requisite rapidly-intermittent contact between the two, and the other that it utilizes the rotation of such rigid conductor as a means for opposing or preventing the movement of its own supports in the direction of rotation of the receptacle, thereby securing, among other things, an approximately constant relative movement between the parts, a feature which in devices of this kind is often very desirable.

Referring to the figure, A designates a receptacle, usually of iron or steel and mounted in any suitable manner, as by trunnions B B, having bearings in standards C C, so as to be capable of rapid rotation about a horizontal axis.

The receptacle is divided into two parts insulated by a washer D and held together by insulated bolts E with nuts F. These two parts are electrically connected, respectively with the two terminals of the apparatus, and by means of brushes X Y, bearing at any suitable points on the two parts of the receptacle, the circuit-controller is connected with the wires of a circuit.

Any convenient means may be employed to rotate the receptacle; but a simple way to effect this is to surround the same with a field-magnet G and to make the receptacle itself the armature of an electric motor or else to secure to it armature-cores, as H.

A body I is supported by trunnions J, having bearings in the ends of the receptacle and concentric with the axis of rotation of the same. The weight of the body I being eccentric to this axis tends to oppose its turning about the axis when the receptacle is rotated.

Upon the body or support I, but insulated therefrom, is secured a vertical standard K, in which there is a freely-rotatable spindle L, carrying a disc M, with radial arms inclined to the plane of the disc, so as to form vanes N. Arms O P are also secured to the body I and are formed with or carry at their ends ducts or tubes Q, with one end directed toward and opening upon the vanes N, and the other end close to the inner wall of the receptacle and opening in the direction opposite to that of the rotation of the receptacle.

A suitable quantity of mercury R is placed in the receptacle before the latter is sealed or closed.

The operation of the device is as follows: The receptacle is started in rotation, and as it acquires a high velocity the mercury or other conducting fluid R is caused by centrifugal action to distribute itself in a layer over the inner peripheral surface of the receptacle. As the tubes or ducts Q do not take part in the rotation of the fluid, being held at the start by the weighted body I, they take up the mercury as soon as it is carried to the points where the ducts open and discharge it upon the vanes of the disc M. By this means the disc is set in rapid rotation, establishing the contact between the two sides of the receptacle which constitute the two terminals of the circuit-controller whenever the two streams or jets of fluid are simultaneously in contact with the vanes, but breaking the contact whenever the jets discharge through the spaces between the vanes. The chief object of employing more than one insulated jet is to secure a higher velocity of approach and separation. The disc M, having acquired a very rapid rotation, operates to prevent by gyrostatic action any tendency of the body I to rotate or oscillate, as such movement would change the plane of rotation of the disc. The movement of the parts, therefore, and the operation of the device as a whole are very steady and uniform, and a material practical advantage is thereby secured. The speed of the disc will be chiefly dependent on the velocity of the streams and pitch of the blades, and it is of course necessary in order to produce a constant speed of rotation of the disc that the velocity of the streams be constant. This is accomplished by rotating the receptacle with a constant speed; but when this is impracticable and the uniformity of motion of the disk very desirable special means are resorted to to secure this result, as by providing overflowing-reservoirs V V, as indicated by dotted lines, from which the fluid issues upon the vanes with constant velocity, though the speed of the receptacle may vary between wide limits.

In Fig. 4 is shown a central vertical section of an improved circuit controller and Fig. 5 represents the latest and most preferred form, showing it in connection with the remaining parts of the apparatus illustrated diagrammatically. In these forms the receptacle contains both a conducting and a non-conducting fluid, the former being the heavier, and the terminals are maintained in such relations that the electrical connection between them is made and broken by the successive immersion of the contact-points into and their withdrawal from the conducting through the non-conducting fluid. These relations are best maintained by such construction of the receptacle that the distribution of the two fluids necessary for the proper operation of the device may be preserved by centrifugal action and the rotation of the other terminal effected by the movement of the fluids in relation to it.

To secure the conditions necessary for the accomplishment of the objects of the invention, various mechanical expedients may be resorted to; but the best and most practicable device for the purpose appeared to Mr. Tesla to be a hollow wheel or drum mounted so as to be rotated at any desired speed and containing a conducting fluid, such as mercury or an electrolyte, which by the rotation of the drum is thrown by centrifugal force outward to the inner periphery of the same, and a sufficient quantity of a lighter non-conducting or poorly-conductive fluid, such as water or oil, which by the centrifugal action is maintained on the surface of the heavier conducting fluid and tends to prevent the

occurrence of arcs between the contact-points and the conducting fluid.

A central opening is formed in one side of the drum, through which enters an arm carrying a disc with peripheral projections or vanes which when the drum is rotated project to a sufficient extent toward or into the conducting fluid to effect the makes and breaks of the circuit.

The motion of the fluid within the drum causes the disc to rotate and its projections or vanes to make and break the circuit with a rapidity which may be very great. In fact, when the drum is rotated at a high rate of speed, the fluid conductor may become in its effect similar to a solid body, upon which the conducting disc rolls so that the conducting fluid might be dispensed with.

In order to insure the proper immersion of the projections into the fluid to compensate for wear and at the same time to secure a yielding pressure between the fluid and the disc, it is desirable to employ for the disc some form of spring connection or support which will exert a force tending to force it in contact with the fluid.

Referring to Fig. 4, the various parts are mounted on a base, which contains the condenser, and comprise a transformer with primary and secondary coils, one or more self-induction coils, a small electromagnetic motor D, and the circuit-controller, which is driven by the motor.

The shaft of the motor D extends through a stationary disc E, and to its end is keyed a hollow wheel or drum F, which rotates with it. Two standards G are secured to the disc E and connected by a cross-bar H, from which extends an arm K into the interior of the drum F through a central opening in its side.

To the end of the arm K is secured an arm L, carrying at its free end a disc M with peripheral teeth or projections N. The disc is mounted on any suitable bearings in the arm L, so as to be capable of free rotation.

It is desirable that the disc should admit of adjustment with respect to the inner peripheral surface of the drum, and for this purpose the arm K is secured to a rod O, which passes through supports in the cross-bar H and is adjustable therein by means of threaded nuts P.

The interior of the drum F is tapered or contracted toward the periphery so as to form a narrow trough in which the fluid is confined when the drum is rotated.

R designates the conducting fluid, and S the lighter non-conducting fluid, which are used in the drum. If the proper quantities and proportions of these fluids be introduced into the drum and the latter set in rapid rotation, the two fluids will distribute themselves under the action of centrifugal force around the drum in the manner shown in the figure. The arm K is adjusted so that the teeth or projections on the disc M will just enter the conducting fluid, and by the action of either or both the disc will be rapidly rotated. Its teeth are so arranged that no two are simultaneously in contact with the conducting fluid, but come into the same successively. If, therefore, one part of the circuit be connected to the drum, as by a contact strip or brush T, and the other part to the disc M, or to any part, as the standards G, which are insulated from the frame of the apparatus and in metallic connection with the disc M, the circuit will be made and broken with a rapidity which may obviously be made enormously high. The presence of the non-conducting fluid on the surface of the other operates to prevent the occurrence of sparks as the teeth N leave the latter and also to prevent the current from leaping across the space between the teeth and the conductor as the two approach.

The diagram of circuit connections shown in Fig. 5 will serve to illustrate the purpose and mode of operation of the latest device. Let f f be the conductors from a source of current, each including a self-induction coil C C' and connected with the arms L and L' and with two conductors B' B'', respectively. Then during the periods when the circuit is completed between the two arms L L' the coils C C' store energy, which on the interruption of said circuit rushes into and charges the condensers. These latter during the periods when the circuit is closed between arms L and L' discharge through the primary A', and induce by such discharge currents in the secondary A'', which are utilized for any purpose for which they may be suited, as in operating vacuum-tubes X or suitable lamps Y. It will be understood that the rotating drum may be mounted in a horizontal or other plane.

The McGurty High Speed Electric System for Mail and Express Service.

DURING the past few weeks a very interesting series of tests have been carried on at Jersey City Heights with a model car or carrier invented by Mr. J. H. McGurty, of Jersey City. For this purpose a circular track, one-quarter of a mile in length, has been constructed at the corner of Central and Manhattan avenues, and around this track the miniature car speeds

McGURTY ELECTRIC MAIL AND EXPRESS RAILROAD.

at a marvelous rate, fulfilling the expectations of the inventor and his friends, as well as suggesting the possibility of a commercially successful system of electric express service. The system invented by Mr. McGurty is for the purpose of carrying mail, newspapers and general express matter at a high rate of speed, embodying devices to have the car stop at any desired station and doing away with an attendant on the car. To accomplish these desirable features, Mr. McGurty has invented several new and interesting devices such as automatic controllers, a novel trolley, insulated sections and brake, all of which will be referred to later on.

It is proposed to run the cars at a speed of 120 miles per hour, but the model car shown in the illustrations, which is box-shaped and pointed at one end, is 5 feet long, 3 feet high and 2 feet wide, and weighs 530 pounds, will not run at this speed. It does, however, with 6-inch wheels, attain a speed of eighteen miles per hour on this "continuous curve" track. The practical car will probably be 30 feet in length and have a capacity of about 40,000 pounds.

The inventor, who has carefully worked out every detail of his scheme, claims as new an alternating current motor, one of which is mounted directly on the front and one on the rear axle of the car. On board of the car is an automatic rheostat for starting the car, there being no attendant, and this rheostat embodies a mechanism by means of which the car can be started as slowly or rapidly as is desired, bringing it up to speed in one or two minutes or even a fractional part of one minute. There is further provided an ingenious electric brake which goes into action as soon as the current is applied to it, and is released when the current is shut off. It can be so regulated by springs as to stop the car at a definite predetermined place and any desired time after the current is applied or shut off. An automatic controller is also placed on the car which reduces the speed of the car when turning corners, or down grades, or when approaching stations. This again becomes a vital feature, considering the possibility of derailment or the acquirement of too high a rate of acceleration. There is also provided a switch under the control of an attendant or tele-

graph operator at the several stations along the route, by means of which the car can be brought to a stop at the required station or caused to pass by it, as desired. This switch is so connected with the conductor or line wire as to cut any section of it out of circuit without interrupting the main circuit and cutting off the supply of electrical energy from other cars at remote points along the line. For this reason the track is divided into as many sections as there are stations along the line, and each station is provided with an insulated circuit breaker for the control of the section at each side of it. The trolley wire, as will be seen from the figure, is supported by a specially designed trolley clip between the tracks, and as the car is intended to run at a high rate of speed, the inventor has adopted a three-wheel trolley which cannot possibly leave the wire.

Having now given a general description of the several devices employed by Mr. McGurty, a general idea of their employment by looking into the method of operation of the system is in order. The cars are sent away by a train dispatcher from one end of the line. He instructs the operator at the station where the car is to be stopped that the car has started on its journey and should be stopped at his station. The operator then throws his station switch, thereby cutting the current off from a section of track near the station. The car, arriving at the station, will find the track in this condition and will automatically have the brakes applied and stop at the appointed place. When it is again ready to proceed on its onward journey the operator opens his switch and the car is started, stopping at any station when so desired or passing through it when no switch is thrown. It is, of course, necessary to use the ordinary block system, allowing only one car to be on any one section at one time; in other words, to have the cars one station apart. It is also necessary to send the "through" cars ahead and have the local cars follow. A car can, of course, be taken out of the line and be returned, the road being double-tracked.

We see, therefore, that all the requirements of a successful express service are fulfilled in this system which, it is claimed, has demonstrated its practicability on a small scale. Mr. McGurty is making further experiments and constantly improving his devices, and hopes soon to have a line constructed between Jersey City and Philadelphia, carrying mail and express matter between these two cities and stopping at a number of intermediate points. Mr. McGurty has been working on this scheme

McGURTY ELECTRIC MAIL AND EXPRESS CAR.

for a number of years, and being an experienced train dispatcher, knows the exacting requirements of a mail or express service. Further developments of his system will be awaited with a great deal of interest by everybody.

BIRMINGHAM, ALA. The Birmingham Railway and Electric Co., having suffered from the frequent theft of its copper wire rail bonds, has given up their use and will rebond the road in conformity with modern and latest practice.

Power Consumption in Electric Railroading—II.¹

BY S. T. DODD.

TO return, however, to the question with which we started—How many pounds of pull does it take to move a train of a certain weight at a certain velocity? The formulæ which steam railroad engineers have developed have been, in some cases, based on hundreds of experiments; but, on account of the widely differing nature of track and train construction, the formulæ differ widely from each other both in their form and in their final results, and without intending to criticise the older branch of railroad engineering, I wish to collect here some of the best known of these formulæ and compare them with readings which we have obtained in electric railroad work.

(1) One of the oldest formulæ with which I am familiar was proposed by Mr. D. K. Clark, and is of the form $(8'' + \frac{V^2}{178})W$, V being the speed of train in miles per hour and W the weight of train in tons of 2,000 pounds.

(2) Another form proposed by Prof. Rankine is of the form $\{5.35 + .268 + (V-10)\}(T + 2E)$

T being the weight of the train behind the engine and E the weight of the engine and tender. You will note that Prof. Rankine's formula is a straight line, the resistance being proportional to the velocity above 10 miles per hour and a constant quantity below that. He also recognizes the importance of the head resistance, the "pace-making" effort of the engine.

(3) A formula proposed by Mr. W. H. Searles based on his experiments, and of which Mr. Wellington says it has a "wonderful range of application to all speeds, condition and classes of trains," is of the form $4.82W + .00535V^2W + .0004783V^3E^2$.

(4) The most complete and accurate set of experiments with which I am familiar were made by Mr. A. M. Wellington.

The method used by Mr. Wellington, the gravity method, is free from the disadvantages I have quoted, and is as nearly theoretically perfect as we can expect in work of this nature. The method is based on the well known principle that a body moving down a frictionless inclined plane will have acquired the same velocity at any point of the incline as if it had fallen freely through a perpendicular distance equal to the amount of its descent.

Given a train moving at the top of a grade with a measured velocity, if steam is shut off and the train allowed to slide down the grade with gravity as its only accelerating force, and if measurements of the velocity are made at various points on the grade, the difference between these velocities and the theoretical velocity due to the difference of levels will give us a measure of the retarding forces experienced by the train. Mr. Wellington goes further perhaps than any one else has done. He divides the frictional resistance experienced by a moving train into (a) Rolling Friction, or the friction of the journals and that between wheel and rail—a quantity independent of the speed. (b) Head Resistance, or the atmospheric resistance experienced by the first car of the train (c) Side Resistance, or the resistance offered by the atmosphere to the several cars of the train. (d) Oscillating Resistance, or increased journal and rolling friction, depending on the speed.

The formula he develops takes account of all these and is of the form $4W + .28V^2 + .03V^2C + .005V^2W$. C in this formula representing the number of cars in the train.

For sake of comparison I have collected in the table Fig. 2 the results of about twenty observations which I consider the most trustworthy I have been able to get. These observations have all been made on interurban cars running on T rails over a level track at a uniform speed.

In this table the first column gives the number of cars composing the train, the second the speed in miles per hour, the third the total weight of the train, and the fourth the traction co-efficient or horizontal effort per ton of train as calculated from the current consumption. The succeeding columns give the results of the formulæ which I have already quoted applied to these particular cases. The formulæ themselves are repeated at the foot of the table.

It will be noticed that the formula of Mr. Clark is too low in every case to correspond to these observations. The common fault of the other three formulæ is that the velocity plays too important a part in them. At speeds in the neighborhood of 50 miles per hour their results are too high, and at 25 miles per hour

they are too low. This is particularly the case with the formula of Mr. Searles and Mr. Wellington where the velocity enters as the square.

I do not propose to base a formula on the results of about twenty experiments, but, as I have said, these observations are the most trustworthy that I have been able to collect, and it may be of interest to try and find a formula which shall combine their results more nearly than those that have been already proposed. By plotting these results I have decided on the following formula as expressing as nearly as possible the results of these observations.

For a single motor car weighing E tons, pulling trailers weighing T tons, the resistance due to the motor car is $(18 + .2V)E$ and that due to the trailers is $(7 + .2V)T$. The results of this formula have been worked out in the last column,

TRAIN RESISTANCE

Clark $(8 + \frac{V^2}{178}) \times W$

Rankine $\{5.35 + .27(V-10)\}(T + 2E)$

Searles $4.82W + .00535V^2W + .0004783V^3E^2$
(Head) (Side) (Oscillation)

Wellington $4W + .28V^2 + .03V^2C + .005V^2W$

Proposed $(18 + .2V)E + (7 + .2V)T$

V — Speed in Miles per Hour

C — Number of Cars in Train

E — Weight of Engine or Motor Car in Tons of 2000 Lbs.

T — " " Trailer Cars " " " "

W — " " Whole Train $E + T$

Elect. Eng'r. N. Y.

FIG. 2.

and by comparing with the observations in column 4 they will be seen to give a very fair agreement.

In conclusion to this part of the subject, I would say that as far as my own observations go, for ordinary interurban cars running on straight and level T rails, with roadbed of modern construction, the formula $(18 + .2V)E + (7 + .2V)T$ expresses very fairly the train resistance between 25 and 50 miles per hour, and while I do not mean to say these experiments are exhaustive, I hope this statement may be of assistance to other observers in collecting and stating the results of their observations.

Fresh-Air Work by Electricity.

A MAN who is prominently identified with the banking and street railroad business of Brooklyn did some "fresh-air work" recently which was highly satisfactory and, as he said, demonstrated that there were more ways of doing good than "buying paper dolls for blind babies." "We had heard of the illness of a woman and her little one," said the fresh-air man, "and that there was little hope for the recovery of the mother. Everybody felt sorry, and all sorts of plans were suggested for making the poor woman more comfortable. Baskets containing dainties were sent, and boxes and bundles of more dainties followed. I

¹A paper read before the Civil Engineers' Club, Cleveland, Ohio.

proposed fresh air, and went to work at once to secure it. I had a wire run from the electric line near our house, in Monroe place, to the sick chamber, had an electric fan placed at the foot of the invalid's bed, and my fresh-air scheme reduced the patient's temperature in a short time, and the doctor thinks it may have had much to do with her improved condition. There must be many places in this large city during the extreme weather where a similar gift would do much good, and for that reason I am anxious to have people know about my 'fresh-air' scheme."

NEWS & NOTES

The Modern Round House Turn-Table—The Westinghouse Electric "Donkey."

THE economies of railway management do not end with the adoption of the high-pressure compound locomotive, or the hundred other contrivances which have been born of necessity, but go on and on, always finding a way to eliminate here or there an unnecessary expenditure. The latest economic development is the adaptation of the electric motor to turn-tables, called the Westinghouse turn-table "donkey." The simplicity of the device and the method of operating it is plainly evidenced in the illustrations. It is the product of the Westinghouse Electric and Manufacturing Company, and consists of their "series reversible" 10 h. p. motor, mounted within a heavy cast-iron frame, having a traction wheel which rests upon the rail of the turn-table pit. Power is transmitted to this wheel through double reduction gears. The "donkey" frame is connected by drawbar

alternating or direct and of any standard voltage, is supplied by wires brought to a suitable contact overhead and then led to the controller.

As no changes in the turn-table are required for installing the turn-table "donkey," the connections between frame of the latter and the turn-table girder being very simple, the cost of installation is low. As compared with the steam-operated turn-table, it is apparent, even to the layman, that electrical power has the advantage, as it is a well-recognized fact that the small portable boiler and engine are extremely wasteful of fuel, besides being a source of danger and requiring constant expert attention.

The comparison with turn-tables operated by push poles is no less interesting. In one of the installations, located at an important division point, it was necessary to turn 176 engines each twenty-four hours, or about 7 per hour. Previous to installing this "donkey," push poles were used, requiring the services of four men, and the operation was a slow one at best. Now one man does the work in a much shorter time. With turn-table "light," the "donkey" will make a complete revolution in 30 seconds, while with a ten-wheel locomotive on the table, weighing, with tender, 100 tons, a complete revolution is made in 45 seconds. We therefore have the following summary:

Engines turned per day.....	176
Men required	4
Average time, each man	5 min.
Total time per engine (5 min. $\times$ 4 men).....	20 min.
Total time for 176 engines.....	59 hrs.
Total time for 176 engines with electric donkey.....	24 hrs.
Time saved	35 hrs.
35 hours at 12½¢., amount saved per day.....	\$4.37

The above calculations assume that the men are employed in wiping engines while not employed in operating turn-table;

VARIOUS VIEWS OF THE WESTINGHOUSE ELECTRIC TURN TABLE.

and pin to one end of the turn-table at the side, sufficient traction for the driving wheel being secured through the weight of the machine, which is 3,700 pounds. Wires are run from the "donkey" to a small platform, located at one side of the centre of the turn-table, or other convenient place, at which point is installed a controlling rheostat. By means of this controller the "donkey" may be operated in either direction and its speed controlled at will by simply moving a single lever to one or the other side of a neutral point. Current which may be supplied from the shop lighting or other convenient circuits, and may be either

otherwise the comparison would be still more favorable to electrical operation.

The assumption of five minutes per man on the average is conservative. It is plain that the 35 hours saved would supply two day and two night men as wipers on shifts of 8 hours each.

It is stated that actual tests have shown that the power consumed by the electric "donkey" is the equivalent of one-half h. p. per hour. Assuming 6 pounds of coal per h. p. with coal at \$2 per ton, the cost of turning each locomotive would be 3-10 cents, or 53 cents for 176 locomotives.

Fourth Annual Meeting of the Ohio Electric Light Association.

A **HIGHLY** successful meeting of the Ohio Electric Light Association, being the fourth annual, was held at the West House, Sandusky, O., when a number of good papers and of pleasant excursions were greatly enjoyed by a large gathering of members and friends, inclusive of several ladies.

Among those present at the Ohio Electric Light Association meeting were: W. B. Chapman, Akron St. Ry. & Ill'g Co.; E. H. McKnight, Bowling Green El. Lt. & P. Co.; H. A. Schlicht, secy., Bellevue Lt. & P. Co.; H. C. Fogle, supt., Canton Lt. Ht. & P. Co.; J. M. Plaisted, supt., J. Q. Brown, secy., Columbus Elec. Co.; A. W. Field, secy., Columbus Edison El. Ill'g Co.; Sam'l Scoville, M. E. Turner, Cleveland El. Ill'g Co.; W. F. Raber, Citizens' El. Ry., Lt. & P. Co., Mansfield, O.; E. F. Gwynn, gen. mgr., Delaware El. Lt. & P. Co.; Albert Thomas, supt., Dayton El. Lt. Co.; C. Schwartz, mgr., Fostoria Lt. & P. Co.; A. F. Dickinson, pres., Geneva El. Lt. Co.; D. L. Gaskill, pres., H. C. Ayres, supt., Greenville El. Lt. & P. Co.; C. Smith, Hancock Lt. & P. Co.; M. Cook, Hillsboro Lt. & P. Co.; W. D. Packard, secy., Robt. E. Gorton, P. A., D. W. Low, Jefferson Lt. & P. Co.; Thos. Espy, pres., Frank Espy, electrician, Kenton Gas & El. Co.; George Mott, pres., Lancaster El. Lt. Co.; John E. Townsend, supt., Lima El. Lt. & P. Co.; B. P. Foster, secy., Northern Gas & El. Co., Norwalk; L. Culver, supt., Northern Gas & El. Co., Norwalk, O.; Dr. A. G. Henry, pres., No. Baltimore El. Lt. & P. Co.; H. K. Wood, pres., S. M. Rust, supt., Piqua El. Co.; E. S. Trussell, gen. mgr., Pomeroy & Middleport El. Co.; John H. Miller, supt., Springfield Lt. & P. Co.; Emil G. Schmidt, gen. supt., H. N. Sloat, electrician, Sandusky El. Lt. Co.; W. S. Smith, E. G. Bechtol, Toledo El. Co.; C. E. Inman, supt., Warren El. Lt. & P. Co.; W. F. Hubbell, Wauseon El. Co.; B. P. Holmes, gen. mgr., Youngstown El. Lt. Co.; S. Griffin, pres., Lake Erie El. Lt. Co., Lorain, O. Also the following supply people: F. A. Kelly, Gen. El. Co., Cincinnati; H. W. Hillman, Gen. El. Co., Schenectady, N. Y.; W. F. Hayes, Gen. El. Co., Cincinnati; C. J. Wells, Chicago; D. W. Low, Packard Lamp Co., New York; Geo. C. Kunz, Bradford Belting Co., Cincinnati; H. E. Adams, Illinois El. Co.

President Wood, of Piqua, O., made a brief but earnest and witty address opening the convention, in which he emphasized the good work that such an Association had done and could do, in such matters as the municipal plant agitation and in the interchange of ideas and experiences. The growth of the Association had been as follows: 1895, members 37; in 1896, 43; in 1897, 49; and 1898, no fewer than 61. He said: "The outlook for the near future opens up with interest and promise to all of us. With the improvement in business which will soon follow, the demand for more light and power will be made upon us, and we should prepare our stations to meet the demand in a way that will reflect credit upon the light and power furnished, thereby giving satisfaction to the customer and profit to the stockholder." After thanking his fellow officers and the Executive Committee, he declared the fourth annual convention open.

Among the papers read was an excellent one by Mr. C. D. Haskins, of Boston, on "The Meter's Relation to the Dividend," dealing with the selection of meters, their installation, questions of temperature, maintenance, testing, cleaning and inspecting. He also discussed the two-rate system and the prepayment meter.

Mr. M. E. Turner, of Cleveland, O., read an admirable paper on "Some Suggestions Relative to Determining the Cost of Electric Supply," in which he developed the "Wright Demand Method" of charging a consumer for current, showing that it was based on the proportioning of all expenses into those which are fixed and those which vary with the output of the station. He went into these different expenses with great detail and minuteness.

Mr. Ernst J. Berg read a very suggestive paper on the "Long

Distance Transmission of Power," devoted chiefly to questions connected with the combination of power transmission for incidental motor load, and with transmission for lighting, considering these under their various aspects. Matters of proper frequency were discussed and arguments were put forward in favor of single phase distribution.

Mr. J. H. Perkins read a paper on "Comparative Commercial Qualities of Old and Modern Transformers as Applied to an Exchange." The figures shown as to the saving effected were remarkable, typical, actual cases being taken.

Prof. E. P. Roberts presented a careful study of "Positive and Negative Economies in the operation of Small Electric Light Plants." Many points of possible economy and of beneficial change were brought out.

The discussions throughout the meeting were pertinent and interesting.

The following officers were elected for 1898-9: President, Emil G. Schmidt, Sandusky, O.; vice-president, B. P. Holmes, Youngstown, O.; secretary and treasurer, Samuel Scovil, Cleveland, O. Executive Committee—H. K. Wood, Piqua, O.; B. P. Foster, Norwalk, O.; George Matt, Lancaster, O.; E. H. McKnight, Middletown, O.; S. Griffin, Lorain, O. Finance Committee—Albert Thomas, Dayton, O.; Thomas Espy, Kenton, O.; Jno. E. Townsend, Lima, O.

Cleveland was chosen as the place for the next meeting, the date to be fixed by the Executive Committee.

The usual resolutions of thanks were adopted, and a tribute was paid to Mr. Wood, the retiring president. The meeting was the best that the Association has ever had.

The New Welsbach Incandescent Lamp Filament.

THE German Journal for Gas Lighting of recent date—reports Consul General Mason, of Frankfort, Germany—contains some highly interesting information upon what is perhaps the most important new topic in the science of illumination, namely, the improved incandescent filament for electric lamps, which has just been announced by Dr. Auer von Welsbach, the distinguished inventor of the incandescent gaslight which bears his name. It was but natural that, having perfected the device which increases so remarkably the illuminating power of gas, Dr. von Welsbach should seek to develop some similar improvement for the application of electrical currents to illuminating purposes.

This, he appears, from the somewhat meagre published accounts, to have found in a filament of osmium, one of the rare metals, which, besides being the densest of all metals, is the most refractory, being infusible at any except the highest attainable temperatures. Osmium is found native as an alloy in certain ores of platinum and iridium. It is a hard, bluish-gray metal, with an atomic weight of 191.1, and the enormous specific gravity of 22.477, the heaviest substance known. Its tetroxide has a strong odor of chlorine, from which circumstance its name was originally derived.

But the property which must have suggested osmium as the material of the new electrical filament was its practical infusibility, its known resistance to temperatures in which platinum and iridium volatilize and disappear. It is well known that the intensity of light emitted by an incandescent substance increases rapidly with its absolute temperature. By heating osmium in a vacuum with an electrical current strong enough to volatilize platinum, it attains a luminosity hitherto almost unknown, emitting a white light of agreeable quality and color, but of great intensity.

So far as can be inferred from what has been published, the experiments of Dr. von Welsbach go quite beyond the employment of a naked osmium filament, and include coating the metal with a refractory oxide like thoria.

It has long been known that a platinum wire or filament, through which a sufficiently strong current is passed, attains a white heat and then suddenly melts. If, however, the filament be coated with a highly refractory oxide like thoria, the temperature required to melt it is greatly increased, for the reason that part of the electrical energy is withdrawn from the metal to its oxide coating and is radiated in the forms of light and heat. Precisely the same result happens when the filament coated with oxide is of osmium, instead of platinum, and the

resistance of the filament is still further increased to the extent that osmium is in itself more infusible than platinum.

There is thus obtained a filament capable of sustaining a temperature and consequent intensity of illumination hitherto unachieved by such means, and it is this which forms the germ of the present invention of Dr. von Welsbach. It has been noted in his experiments that osmium used for this purpose must be almost chemically pure, and that commercial forms of that rare and costly metal require, before using, to be cleansed as far as possible of all impurities except platinum, a small admixture of which renders the osmium more elastic without sensibly diminishing its infusibility. The whole effect of the invention, if practically applied, will be to advance in an important degree the limit of electrical energy which may be used in incandescent lighting and thus reach a new standard of economy in the production of artificial light, which is cheapest at the intensity obtainable only at high temperatures.

Osmium, according to the trade catalogue of a leading German chemist, costs \$1.10 for 20 grains; so that if the new filament should become successful in general use, there will be a demand for a larger supply of that metal at a more moderate price.

The Economical Carboning of Arc Lamps.

BY W. J. CLARKE.

FOR some unaccountable reason it seems that but few lighting stations are aware of the fact that it is possible to reduce greatly their operating expenses by giving proper attention and study to the carboning of the arc lamps. The large majority of the stations have for years been using double carbon lamps, in order that it may be possible for them to operate the lamps all night, or for two nights where the lights are extinguished at midnight. Now it is quite possible to give just as good if not better results by so carboning the lamps that a double lamp will run two whole nights of 14 hours each, and in this way it will be readily seen that the number of trimmers will be reduced one-half, on account of the fact that while one man can carbon, say 50 lamps per day, where each lamp will only burn one night, it is quite possible for the same trimmer to carbon just double the number of lamps if they are so carboned as to burn two whole nights. This reduction in trimmers is accomplished by each man taking a circuit of 100 lamps instead of 50, and carboning one-half of them each day.

It may at first seem strange that the number of hours that an arc lamp will burn may be nearly doubled by a slight change in the carboning as well as in the current; but the writer has proved again and again by practical experience that this can be quite readily accomplished, by using five-eighths-inch plain carbons in the upper holders and one-half-inch copper-coated carbons in the lower holders, and then reducing the current on the line from $9\frac{1}{2}$ to 9 amperes. It will, of course, be necessary as soon as this is done to alter slightly the adjustments of the lamps, but the larger carbon in the upper holders has the effect of giving the appearance of a much steadier and stronger light than formerly, so that the city authorities usually consider that the service has been greatly improved just as soon as the change has been made.

Sixth Annual Meeting of the Society for the Promotion of Engineering Education.

THE sixth annual meeting of the Society for the Promotion of Engineering Education was held in Room 22 of the Walker Building, Massachusetts Institute of Technology, Copley square, Boston, Mass., on August 18, 19 and 20, 1898.

After a meeting of the council at 9 a. m. on Thursday, August 18, the general meeting was called to order at 9:30 by President John B. Johnson, Professor of Civil Engineering, Washington University. After the routine business had been disposed of, such as the reports of officers and election of members, the president read his address, entitled "A Higher Industrial and

Commercial Education as an Essential Condition of Our Future Material Prosperity."

The following papers were then read: "The Mutual Adjustment of Class-room and Laboratory Instruction," by Prof. Gaetano Lanza; "The Mounting of a Spherical Blackboard," by Prof. A. E. Haynes, and "Notes on the Organization of an Engineering Laboratory," by Prof. H. B. Smith.

Thursday afternoon was devoted to sightseeing and a number of excursions and trips of inspection were indulged in by the members and their friends.

In the evening an interesting paper was read by Prof. R. H. Thurston on "The Correct Theory and Method of Organization and Conduct of Professional Schools." The committee on entrance requirements, of which Prof. H. W. Tyler is chairman, made their report.

On Friday morning after business had been transacted, the members listened to the following papers: "Some Phases of Engineering Education in the South," by Prof. J. J. Wilmore; "The Study of Electricity in Courses Other than Electrical," by Prof. J. P. Jackson; "A Course in Industrial Chemistry for Technical Schools," by Mr. F. L. Dunlap; "A New Laboratory Apparatus for Illustrating Longitudinal Impact," by Prof. W. K. Hatt.

The afternoon was devoted to sightseeing and in the evening the following papers were read: "The Direct Study of Thermo-dynamics," by Prof. S. A. Reeve; "Laboratory Instruction in Electrical Engineering," by Prof. R. B. Owens; "A Course in Highway Engineering for Civil Engineers," by Prof. W. R. Hoag; "Notes on Some Methods in Use in an Engineering Laboratory," by Prof. F. C. Caldwell.

The session was resumed on Saturday morning when these papers were read: "The Claims of Sanitary Science to a Place in the Curriculum of Engineering Education," by Prof. W. T. Sedgwick; "Undergraduate Thesis Work," by Prof. Edgar Marburg; "The Construction of Models by Students as an Aid in Teaching Descriptive Geometry," by Assoc. Prof. Henry S. Jacoby, and "The Training of Engineers for the Maintenance of Way Department on Railroads."

A business meeting was then held at which committees were appointed and officers for the ensuing year were elected. The attendance was excellent and the papers were ably discussed. The meeting was adjourned sine die on Saturday afternoon, August 20.

Electrical Course at Pratt Institute.

We wish to call attention to the admirable work done in the science and technology department of the Pratt Institute, Brooklyn, N. Y., in their two-year courses in drawing and machine design and applied electricity. They are filling a want that has for a long time been felt in the field of technical education. Their courses are not intended to train expert engineers or specialists and their students are men who have had but little previous theoretical knowledge and cannot pass the difficult mathematical entrance examinations that are required by the higher educational institutions.

They start with low requirements for admission and in two years give their students a thorough training in the theory and practice of mechanical and electrical work, of which the record of their graduates is ample proof. Mr. Arthur L. Williston is director of the department and has brought the same up to a high standard of proficiency. We also take this opportunity of commenting on the excellent evening courses which have been inaugurated at the Pratt Institute in which carpentry, machine work, plumbing and painting are taught for the insignificant tuition fee of \$15 for six months. There are also evening classes in mechanical drawing, mechanism, physics, chemistry, applied electricity and the steam engine, for which a tuition fee of \$5 is charged for a course covering a period of three months. Circulars giving information on these various courses will be gladly sent to any one on application to the director of the department.

Classified Digest of U. S. Electrical Patents Issued August 9, 1898.

Batteries, Secondary:—

PLATE FOR SECONDARY GALVANIC BATTERIES AND COMPOSITION FOR PRODUCING SAME. Carl Marschner, Berlin, Germany, 608,614. Filed Sept. 30, 1898. An exterior lead frame and a filling composed of an active material, such as lead oxid, and a binding medium, such as amber.

STORAGE BATTERY. John D. Rively, Pittsburg, Pa., 608,714. Filed June 9, 1897. Consists in an outer box or casing having a series of positive and negative plates arranged therein and provided with a fiber or other suitable backing, which serves to form a spongy substance to retain the acid stored in the same, and serves to keep the plates in a moist state.

Conductors, Conduits and Insulators:—

INSULATION OF ELECTRIC WIRES. Joseph A. Poche, New Orleans, La., 608,906. Filed June 22, 1898. An insulation for conductors carrying currents of high potential, consisting of a surrounding insulating-sleeve and two inclosing glass cones, retained by a collar at one end and a nut at the other.

ELECTRIC CABLE. Henry A. Reed, Newark, N. J., 608,911. Filed Oct. 24, 1898. A conductor with an insulating covering and a sheathing or armor consisting of spirally laid wires of non-magnetic metal.

Dynamos and Motors:—

ELECTRIC MOTOR. William H. Powell, Erie, Pa., assignor to the Keystone Electric Co., of Pa., 608,711. Filed Nov. 4, 1897. A device which prevents the sudden rush of current through the motor-armature at starting, and to secure all the necessary starting torque with a current not greater than the normal working current of the motor; also, to combine all the advantages of a compound and a shunt motor by running as a compound machine at starting.

Electric Heating:—

ELECTRICAL COOKING APPARATUS. John B. Cary, Baltimore, Md., assignor of one-half to Marie Clothilde Delavy, Baltimore, Md., 608,952. Filed March 14, 1898. Combination of two boxes each one having therein heating wires and a corrugated tray situated over the wires, and strap-hinges, one member of which is adjustably attached to a box whereby the boxes may be separated and held in a separated position.

Electro-Chemistry:—

APPARATUS FOR HEATING AIR FOR THERAPEUTIC OR OTHER PURPOSES. William Taylor, Edinburgh, Scotland, 608,928. Filed Dec. 21, 1897. The apparatus comprises means for imparting motion to the air or gas, combined with means for heating it.

Lamps and Apparatuses:—

ELECTRIC ARC LAMP. Thomas Spencer, Philadelphia, Pa., 608,723. Filed Sept. 29, 1897. Enclosed arc lamp having its inductance reduced when lamp is started. Solid carbons can be employed. It has a novel clutch and is adapted for alternating currents.

Measurement:—

ELECTRIC METER AND MOTOR. Harry P. Davis, Pittsburg, and Frank Conrad, of Wilkensburg, Pa., assignors to the Westinghouse Electric and Mfg. Co., Pa., 608,842. Filed June 18, 1898. A simple and efficient means whereby a shifting magnetic field may be produced and employed for actuating an armature or secondary member having circuits closed upon themselves and located in such magnetic field at a speed which is proportional to the energy in the circuit with which it is connected.

Miscellaneous:—

ELECTRODYNAMIC APPARATUS FOR OPERATING CLIPPING, BRUSHING OR OTHER MECHANISMS. Warren P. Freeman, New York, assignor to Robert J. Campbell, same place, and Francis Larkin, Jr., Sing Sing, N. Y., 608,768. Filed Aug. 12, 1897. An electrically actuated clipping mechanism, consisting of an electric motor, the field magnet of which forms a casing within which the operating parts are contained.

APPARATUS FOR STORING AND USING SOLAR HEAT. Henry F. Cottle, Boston, Mass., assignor of two-thirds to William Calver, Washington, D. C., and John J. Pratt, Revere, Mass., 608,755. Filed Dec. 11, 1897. Concentrating the sun's rays and causing them to fall upon a suitable heat receiving and retaining body, such as a pile of stones, and then causing the stored heat from said body to fall upon a thermo-electric generator, which converts the energy of heat into energy of electricity, and finally utilizing the electric energy in any suitable manner.

WIRE STRIPPING TOOL. Leroy A. Sell, Philadelphia, Pa., assignor of one-half to Meredith O. Sullivan, same place, 608,919. Filed July 8, 1896; renewed Jan. 26, 1898. A tool consisting of two jaws linked together which grips the wire and strips off the insulation as the wire or support are moved longitudinally in relation to one another.

GENERATOR FOR ELECTRICAL IGNITERS. Benjamin McInnerney, Omaha, Neb., assignor to the McInnerney Mfg. Co., same place, 608,896. Filed March 30, 1898. The combination with the shaft, fly-wheel and electrical igniter of a gas engine, of a yoke swinging upon a bearing, arms extending from the yoke, a permanent magnet and core carried by one of the arms, stop devices limiting the movement of the other arm, and keepers carried by the flywheel.

GENERATOR FOR ELECTRICAL IGNITERS. Benjamin McInnerney, Omaha, Neb., assignor to the McInnerney Mfg. Co., same place, 608,896. Filed March 30, 1898. Similar to above.

STEAM WHISTLE. Forrest A. Davey, Detroit, Mich., assignor of one-half to John G. Patterson, Detroit, Mich., 608,955. Filed June 1, 1897. A specially constructed steam whistle, with an electro-magnet attached to pipe and valve for operating it.

Railways and Appliances:—

SUPPORTING CLIP FOR OVERHEAD ELECTRIC CONDUCTORS. William A. Bartley, Boston, Mass., 608,637. Application filed May 23, 1898. Two separable interlocking members, one of which is arranged to be forced into operative position after the wire is put up, so as to clamp and support it in conjunction with the fixed member.

BOND FOR RAILS. George A. Weber, New York, N. Y., 608,736. Filed Feb. 7, 1898. A bond formed with end portions and a thickened or enlarged part intermediate its ends.

Regulation:—

AUTOMATIC ELECTRIC REGULATOR. Robert Skeen, St. Louis, Mo., 608,721. Filed Oct. 23, 1897. For cutting out automatically one or more devices in a circuit, so as to utilize the available current to operate to full or nearly full efficiency the remainder of the series, and likewise to restore such cut-out devices when the current rises to the predetermined voltage.

Switches, Cut-Outs, Etc.:—

LIGHTNING ARRESTER. John F. Kelly, Pittsfield, Mass., assignor of one-half to Cummings C. Chesney, Pittsfield, Mass., 608,635. Filed Dec. 16, 1895. A lightning arrester consisting of a column of conducting or semi-conducting bodies in bad contact with one another, as a whole practically non-conducting under ordinary electric stress, but under high stresses conducting.

SWITCH FOR VARYING ELECTRIC RESISTANCE. Eduard F. H. Lauckert, London, Eng., assignor to Siemens Brothers & Co., Ltd., London, England, 608,878. Filed Nov. 23, 1897. A switch for varying electrical resistance, consisting of a series of conducting segments connected by successive resistances, and two or more brushes connected to move together but insulated from each other and electrically connected through a resistance.

Telephones:—

TELEGRAPH REPEATER. Henry P. Donnelly, Cincinnati, Ohio, 608,846. Filed June 23, 1897. A mechanism to be employed at a station intermediate of two signaling-stations and to act as a repeater or relay to automatically transmit the signals, thus shortening the length of line operated by one battery.

TELEGRAPHY. George V. Trott, Chicago, Ill., assignor of one-half to Ella M. Cozens, Chicago, Ill., 608,932. Filed Aug. 13, 1897. Railway telegraph system wherein telegraphic instruments may be employed upon moving vehicles to transmit and receive signals.

An "Accident" From Stealing Trolley Rides.

Judge Pennypacker, of the Common Pleas Court, Philadelphia, has handed down an opinion adverse to the interests of small boys who steal trolley rides by hitching on behind. The facts were that Louis Feingold was stealing a ride upon a car of the Philadelphia Traction Company in September, 1895. He had seated himself upon the side step of a summer car, and the conductor observing him from the middle of the car, motioned with his finger and told him to get off. The boy became frightened and fell off while the car was in motion and was run over, a wheel cutting off his foot. Suits were then begun to recover the damages, and at the trial the court instructed the jury to find a verdict for the railroad company. Motions for new trials were made, and it was upon these motions that the decision was rendered. The plaintiffs' counsel contended that it was the duty of the conductor to stop the car and see to it that the plaintiff was put down gently and in such a way that he could not hurt himself.

Judge Pennypacker in his opinion says: "Is there such a duty? We know of no Pennsylvania case which has so held, and the principle does not commend itself to approval. However meritorious it may be to save children and others from impending danger, we are not required to offer our aid under penalty of damages for refusal. To hold that such a duty exists is in effect to say that the cars are run for the benefit of trespassers. To require the stopping of a car in order to put off intruders might be upon certain occasions a great embarrassment to both the company and its passengers. A school of trespassing children could lawfully stop the running of a railroad. The true rule would seem to be that deduced from our cases, and upon which the most of them can be reconciled, that force, or that which is tantamount to it, cannot be used to the injury of child trespassers, but that the responsibility for care over them rests with their parents and guardians."

Damages for Passenger on Electric Car Frightened by Flashes.

OLGO PAULSEN, while a passenger with her niece, twelve years old, upon an open trolley car of the Nassau Electric Railroad Co., Brooklyn, N. Y., becoming alarmed by the flashing from the controller or motor box situated at the front railing of the car, jumped from the car while it was in motion, and fell to the ground, breaking her leg and receiving other severe injuries. In an action brought by her against the railroad company to recover for such injuries, there was evidence tending to show that the flashing was of an unusual character; that the controller was out

of order, a fact which was easily discoverable, and that the car had not been inspected before it left the depot on this trip. A judgment on a verdict given on the trial for plaintiff for \$7,500 was unanimously affirmed by the Second Appellate Division in an opinion by Presiding Justice Goodrich. The court held that the question of the defendant's negligence was properly submitted to the jury, and that the judgment should not be disturbed. It was held that negligence might also be imputed to the railroad company from the fact that the motorman, after the flashing or flaming began, permitted the car to continue its course, without stopping to ascertain the cause of the flame, until a new element of apprehension was reproduced by the burning of the fuse.

Purchase of Municipal Lighting Plant.

A debt for the purchase of an electric light plant for a municipal corporation is held, in *Mayo vs. Washington* (N. C.), 40, L. R. A. 163, not to be one of the "necessary expenses" of the town which can be incurred without a vote of the majority of the qualified voters and legislative authority.

Responsibility for Flywheel Accident.

In the autumn of 1895 a flywheel, eighteen feet in diameter, in the power house of the Albany Railway in the city of Albany, burst or fell to pieces, while in motion, and one of the fragments killed a young man who was in a saloon on the opposite side of the street. In a suit brought to recover damages on account of his death, the Appellate Division of the Supreme Court in the Third Department has just held that the mere fact of the explosion of the wheel was not presumptive evidence of negligence on the part of the owners operating it. The wheel had been purchased directly from the manufacturers and had been safely used for two years. "Some injuries are of such a nature," says Mr. Justice Landon, who writes the opinion, "that the first thought that occurs to the mind is that nothing but carelessness or wilfulness could have produced them." But he thinks that the bursting of a flywheel does not fall within that class. "The explosion does not, in fact, speak for itself and tell us the cause. To punish the defendant because it cannot explain the cause of the explosion is not to punish it because it has done wrong, but may be because it does not know what we wish to find out." In the language of lawyers, the *res ipsa loquitur*, "the thing itself speaks," is said to apply to those cases in which negligence is inferred simply from the occurrence of the accident.

CINCINNATI, O. The B. C. A. has rejected the bill for the \$20 fees for the membership of ex-City Electrician Cabot, in the National Electric Light Association.

Confidence.

The past week has witnessed an intensification of the conditions making for betterment. Bank clearings showed a gain over a year ago of 11 per cent., and 56 per cent. over 1896. Railroad reports are good, Burlington & Quincy increasing its dividend rate to a 6 per cent. basis. Wheat shipments are larger than last season, and crops are excellent. Trade in every section is waking up rapidly under a good Fall demand, and the iron and steel industry is on a boom. Best of all, there is peace.

The stock market has faithfully reflected the improvement, and after enormous transactions and reactions, became steady at a much higher range of prices. On sales of 62,974 shares Western Union went up to 95 $\frac{3}{4}$ and stayed thereabouts. General Electric reached 42 and closed at 41 $\frac{1}{8}$, on sales of 9,115 shares. New York Edison reached 133. In Boston, American Bell Telephone went up to 284 and closed at 282. West End Railroad closed at 87 $\frac{1}{2}$. New York Metropolitan Street Railway closed at 159 $\frac{1}{2}$, but Manhattan fell off, closing at 100 $\frac{1}{2}$. There were rumors of its coming purchase and electrification by the Metropolitan.

General Electric Stock Scaled Down Twenty Millions.

At Schenectady, N. Y., on Aug. 17, the reduction of the capitalization of the General Electric Company was effected at the adjourned stockholders' meeting without any considerable opposition. Mr. T. Jefferson Coolidge, seconded by M. Phelan, made a motion in the form of a resolution, declaring that the capital stock of the General Electric Company be reduced from the present amount to \$20,827,200, which shall consist of 182,760 shares of common stock, par value \$100, and 25,512 shares of preferred stock, par value \$100, the now existing common and preferred stock and the number of shares of each holder being respectively reduced to three-fifths of the present amounts.

Mr. W. L. Putnam, representing the minority preferred stock, moved to adjourn and await the result of the Livermore litigation. The motion was put to a stock vote and lost—243,141 to 9,800. Mr. Putnam also attempted to have a committee appointed to appraise the true valuation of the property, but Messrs. Coolidge and Ames affirmed their reliance on the Board of Directors, who had carefully considered the matter, and this amendment was also lost.

Mr. Putnam protested that the vote was illegal, for four reasons: First, because the charter did not authorize the reduction; second, because such reduction would practically take 40 per cent. from the value of the preferred stock and give it to the common stock; third, because the common shares had been largely overissued and had remained unpaid; fourth, because there was no sufficient justification for reduction on any grounds whatever. Finding that the tide of the reduction movement was too strong to be resisted, Mr. Putnam finally succumbed with a last attempt to have the vote declared void.

President Coffin overruled all these objections. The sworn tellers made their report through Mr. Darling, their chief. President Coffin declared that 243,141 votes were cast in favor of reduction and only 9,800 against it.

ELECTRIC STORAGE BATTERY CO., of Philadelphia, did a business in July, it is stated, of \$200,000, and August is expected to exceed that figure.

Chas. J. Bogue's Marine Projectors and Searchlights.

A number of small pamphlets are being sent to the trade and interested parties by Chas. J. Bogue, 213-214 Centre street, New York, illustrating his line of projectors and searchlights for use on large steamships, and small yachts, as well as for freight and pleasure boats of every description. The lamps on these projectors may be turned in a continuous circle, and the cylinder is snow and waterproof. He also describes the pilot house projector of his electric focusing arc lamps operating singly or in series on 110, 220, or 500 volt circuits. The lamps are made from 1,000 to 10,00 c. p. An aluminum reflector is provided which obliterates all shadows. These lamps are suited for use by photographers, photo engravers, and lithographers, as well as for electric fountains, blue printing, etc. Mr. Bogue also makes a specialty of rewinding armatures, repairing commutators and doing general installation and construction work.

MR. A. O. SCHOONMAKER has issued a very neat illustrated bulletin in regard to his India and amber mica, and giving three very interesting views of the mines from which he draws his supplies. His headquarters are 158 William street, New York, and 1563 Monadnock Building, Chicago.

An Interesting Catalogue on Mica.

It is not often we have such a neat and interesting catalogue to look over as one lately received from the Mica Insulator Company. A short illustrated history of Mica, down from the times of Thales and Mahomet to those of the Anglo-Indian, opens the book. The illustrations in this article give a good idea of the Mica mines of India. There are strange looking ladders crowded with Hindoos passing up mica and water in baskets and jugs, other Hindoos sitting on their haunches, on the open ground, sorting and trimming the transparent crystal; bullock carts loading, and on their way down the mountains, and the mine owners' bungalow.

Micanite is then treated in a very exhaustive manner. It is shown how, by splitting and reassembling the raw laminations of the mica crystals the natural defects are overcome, and a homogeneous material produced. The tables given are useful and instructive. They include "Resistances," "Breakdown Voltages," etc., of a large number of insulators. Other instructive articles have for their titles "Physical Properties of an Insulator," "Armature Notes, Construction of Commutators and one relating to "Field Spools."

The business part of the catalogue includes all the specialties made by the company. Among others, micanite plate, flexible micanite plate, micanite cloth and paper, micanite commutator segments, micanite rings, armature troughs, washers, tubes, spools, cylinders, etc., all too well known to receive special mention. A striking feature—one that shows the extent of the electric railway business of the country, is the fact that a list of complete commutator insulators for fifty-one types of street railway motors is given. Space is also given to the other materials manufactured by the company, including "Empire" oiled papers and cloths, linen and asbestos, etc., and similar materials treated with their "M I C compound." We can advise all electrical engineers interested in the improvements made in electrical insulation to send for this catalogue. They will find it both instructive and useful.

Impulse Water Wheel Company.

The new water wheel catalogue issued by the American Impulse Wheel Company, 120 Liberty street, New York, has just been received, and contains a great deal of valuable and interesting information on the subject of water wheels in general and the impulse wheel manufactured by this company in particular. A great deal of time and thought must have been expended on this book, which will prove of great value to any one interested in the subject of water power and long distance transmission. The catalogue contains data for estimating the head and quantity of water power and speed of water wheels, as well as the construction of pipe lines. There is a chapter on weir measurements and tables for weir dams, power of water and speed for standard wheels, and one on the use of turbines, all accompanied by explanatory notes. A large variety of impulse wheels for various purposes are illustrated, as well as the Lombard governor and the McCormack turbines. Annexed to the catalogue is a table giving the average water pressure in various cities taken from Baker's Manual of American Water Works. The catalogue is handsomely bound, and is a credit to this company which of late years has done such useful work in the developing of water powers of this and other countries. The catalogue will be sent to any one on application.

Allgemeine Elektrizitäts Gesellschaft.

The above company, which might be said to represent to a very large extent, the electric railway development in Germany and adjoining countries, have recently issued a very interesting pamphlet containing a list of roads equipped by them. Fifty-five roads are enumerated, with a total length of track of 1,095 km.; 1,861 motor cars and 12 snow sweepers. Twenty more roads are in course of construction. The tables give the following data of each road: The year the road was opened, name of the company operating the road, its length, distance between tracks, kinds of tracks used, maximum grade, number of motor cars, trailers, motors, boilers, with their evaporating surface; number of steam engines, their capacity; total capacity of the plant, number of generators, their voltage and the total power in kilowatts. It is a valuable pamphlet and one which

gives a splendid idea of the progress of electric railroading abroad.

Smith & Hemenway Company.

A very attractive and useful catalogue has just been issued by the above company, located at 20 Warren street, New York, which contains a mint of information on various kinds of cutlery, such as knives, pliers, razors, etc. A large portion of the catalogue is devoted to a description of the telephone apparatus manufactured by the Ericsson Telephone Company, also located at 20 Warren street. There are shown the desk and interior telephones as well as the long distance transmitter, double pole receiver, Swedish induction coils, and the Ericsson Swedish coal-grain microphone. The catalogue also contains a description of the goods manufactured by the Utica Drop Forge & Tool Company and the Swedish Razor Company.

New York Trade School.

The annual catalogue of the New York Trade School, located on First ave., between 27th and 28th sts., New York, has been received, and contains very interesting details about the splendid work done by the students of this admirable institution during the past few years, and the announcement of the courses for the coming year. These include bricklaying, plastering, plumbing, electrical work, carpentry, house painting, steam fitting, fresco painting, blacksmith work, printing, sign painting, sheet metal cornice work and drawing. Day and night instruction is given for moderate fees which include the use of tools and materials. The system of instruction followed at the school is what is known as the "Auchmuty System, and was originated by the founder. By this system a course is arranged in which both the practical and theoretical branches of the trade are taught, so that not only is the school training quickly acquired, but the scientific principles that underlie the work are also mastered. Mechanics of high skill and long experience act as instructors. Each student receives individual care and attention. The equipment of the respective workshops of the school offers every facility for instructive purposes. Since the New York Trade School was founded, 6,805 young men have attended the school, and during the past five years the annual attendance has averaged over 500 students. The fee for the electrical course is \$16 for the entire course, and is reserved for young men between seventeen and twenty-two years of age. The different divisions included in this course are bell work, burglar alarm systems, electric gas lighting, and electrical wiring, and judging from the work of the students illustrated in the catalogue the instruction seems to be thorough and practical. This catalogue will be sent to any one on application to the school.

Denver Engineering Works.

A very handsome pamphlet has recently been issued by the above company, located at Denver, Col., showing a great variety of steam and electric hoisting plants installed by them. Numerous illustrations of direct-acting hoisting engines are shown and their advantages for different classes of work are pointed out. They also show hoists driven by double engines as well as friction hoists, various kinds of mining hoists and a large number of similar machines driven directly by electric motors. The catalogue also contains several interesting and valuable tables, and the book must certainly prove of value to anyone in need of such apparatus. The catalogue will be sent to anyone on application.

The "Zeitschrift für Elektrochemie."

Since July 1 our esteemed contemporary, the *Zeitschrift für Elektrochemie*, which is edited by Dr. W. Nernst and Prof. W. Borchers, has appeared weekly instead of bi-monthly. This change has been found necessary on account of the number of important articles which it had been found impossible to publish for want of space. The quarterly subscription will, however, remain the same as heretofore.

SCHOENHOFEN BREWING CO., Chicago, has ordered from the Ball Engine Co., Erie, Pa., one 100-horse-power engine, direct connected to Western Electric dynamo.

TRADE NOTES AND NOVELTIES

The C & C Agency in Chicago.

Mr. Martin J. Insull, of Chicago, formerly of the engineering firm of Sargent & Lundy, has been a visitor in New York during the last week. While here Mr. Insull arranged with The C & C Electric Co. to represent them in the Chicago territory, with headquarters in rooms No. 1012 to 1013 Monadnock Block. Sargent & Lundy have during the past year represented The C & C Electric Co. in Chicago, with Mr. Insull in charge of the electrical department, but with Mr. Insull's recent withdrawal from the firm the C & C agency was relinquished. Mr. Insull's long experience in the electrical field, his extensive acquaintance, his thorough familiarity with C & C apparatus, and the general excellence of the product of The C & C Electric Co. assure the success of his efforts.

New G. E. Machine Shop at Schenectady.

WORK on the machine shop of the General Electric Company at Schenectady was begun last week, when ground was broken for what will be a most important addition to the great manufacturing facilities of that company. The contracts have been let to A. & R. Roberts, of the Pencoyd Iron Works, Philadelphia, for the steel construction and to J. J. Turner, of Amsterdam, N. Y., for the masonry, etc. The cost of the new building is estimated at \$175,000. The new machine shop will face on Central avenue, opposite Building No. 15. It will be 653 feet long and 166 feet wide and will be divided into three aisles; the central one having a width of 65 feet, the side aisles being each about 50 feet wide. The total floor space of the building will be not less than 144,250 square feet. It will contain the machinery necessary to handle the very large apparatus which the requirements of modern practice have rendered necessary.

The need of such an addition to the manufacturing facilities of the General Electric Company is realized after a visit to the factory at Schenectady at the present time. The many orders both for large machinery and for large quantities of apparatus, are severely taxing their facilities, and such has been the rush of work that the traveler on the New York Central Railroad as he passes the town at night sees at least half of the buildings lighted up and filled with employees busily engaged in pushing forward to completion the orders in hand. The running of night shifts has been carried on since the beginning of the year, and according to the superintendent, there are few signs of the practice being abandoned for the present. It is expected that the new machine shop will be completed before the end of this year. The machinery will be driven by the current transmitted from Mechanicville, 17 miles distant.

In addition to the new machine shop, the General Electric Company is making several important extensions to other buildings. The new foundry, which was recently begun, is now in position to receive the iron work, the support for the great traveling crane having been erected last week. This building when finished will contain, it is said, the largest foundry under one roof in the world.

ADVERTISERS' HINTS

CROCKER-WHEELER ELECTRIC COMPANY show an excellent illustration of power generator.

WESTERN ELECTRIC COMPANY advertise a speaking tube as being one of the requirements of every thoroughly equipped electrical supply house.

WESTINGHOUSE ELEC. & MFG. COMPANY show illustrations of their Multipolar Generator and Motor.

C & C ELECTRIC COMPANY are advertising a new type of slow speed motor and dynamo to be known hereafter as "P. P."

VICTOR CIRCUIT BREAKERS are advertised by F. A. La Roche & Co.

THE COLUMBIA INCANDESCENT LAMP COMPANY refer to trial orders for their well known make of lamp, and

keep continually a large stock on hand in order that prompt shipments may be made.

J. JONES & SON call attention to their automatic time cut-out which will pay for itself in a short period by the mere economy effected by a sale.

ELECTRIC APPLIANCE COMPANY announce a flexible conduit for interior wiring.

THE GARVIN MACHINE COMPANY show an illustration of a universal milling machine, and announce that they have over a thousand machine tools, both new and second-hand, that are ready for immediate delivery.

WESTERN TELEPHONE CONSTRUCTION CO., Chicago, has considerable to say in regard to the Carty patent.

WESTERN NOTES

ELECTRICAL APPLIANCE CO., Chicago, says: "While iron and steel armored conduit is being used to the exclusion of almost everything else in new conduit work, there is nevertheless a great deal of work where iron armored conduit cannot be used. The most satisfactory substitute under such circumstances is Canvasite flexible conduit. This is particularly useful in wiring or rewiring old buildings and in difficult and out of the way places in new buildings. The Electrical Appliance Company are carrying Canvasite flexible conduit in all sizes from 1/4 inch to 1 1/4 inch and find that it has a ready sale for the above mentioned uses."

THE NEW YORK & OHIO CO., manufacturers of the celebrated Packard transformer, have recently brought out their latest model, which is to be known as "Model 98." The results secured on this new model are noteworthy in the way of transformer regulation and efficiency. The Electric Appliance Company, general Western agents for the Packard transformer are distributing special circulars of the same, giving tabulated results of a number of tests. The manufacturers of this transformer are prepared to guarantee these results on each and every transformer sold, and a large fall trade is looked for on the "Model 98."

THE DEARBORN DRUG & CHEMICAL WORKS, of Chicago, has recently analyzed fourteen boiler feed waters and shipped two carloads of suitable scale solvents to large sugar concerns in the Hawaiian Islands.

THE ELECTRIC APPLIANCE CO. have recently issued a little folder calling attention to their "Self-Contained Automatic Telephone Hook." This hook was designed by the manager of their telephone department and is manufactured exclusively by the Electric Appliance Company. It is claimed that it can be installed in a smaller space than any other hook on the market. Its installation is very easy, as the hook is put together complete in one piece of apparatus; and all that is necessary is to screw it in the telephone box.

GREENMAN ELECTRIC CO., of Sioux Falls, Iowa, is in the market for good electrical agencies in its territory. It has a paid-up capital of \$2,000, and is making and selling electrical supplies, steam and gasoline engines, mechanical supplies, etc. H. K. Greenman is president and manager; M. E. Greenman, vice-president, and E. P. Greenman, secretary and treasurer.

NEW ENGLAND NOTES

THOMAS WESTCOTT is the name of a man against whom the police give warning. One of his recent swindling tricks was to use stationery like that of the Columbia Electrical Co. of Worcester, Mass., with a false statement of change of address, and then order all kinds of goods sent to the "new" address in Boston. One New Jersey firm sent on goods, which Westcott at once turned over to a junk dealer for \$900.

NEW HAVEN, CONN. The New Haven Gas Light Company have placed the contract with the Berlin Iron Bridge Company, of East Berlin, Conn., for their new fireproof coal shed. The building is 60 feet wide and 500 feet long. The framework of the building is steel, so arranged that the coal cars are brought into the building on a track supported by the roof trusses, the idea being to provide the maximum storage at the least expenditure of power and room.

A Novel Job at Adrian, Mich.

Clarence Belcher, an 11-year-old lad of Rome Center, has a unique job with the electric lighting company, says the Adrian Times. He comes here once a year and works about two days and a half in the capacity of "oiler" of the street lamps. The lamp is lowered to the ground, Clarence gets astride the iron shade, and is then drawn up to the wire, where he oils the pulleys. The little fellow has all kinds of nerve and secured his present position last year through his reputation as a climber. He gets 50 cents a day.

Telephony from Paris to Berlin.

A long distance telephone service is being arranged to connect Paris and Berlin. Messages will be received at Brussels and thence transmitted to the two termini. It will be interesting to see what kind of treason will be sent across by wire from Berlin to Paris when this new service is got into operation. At any rate, it will be a capital thing for Brussels, as this city will thus become the centre of telephonic communications in the middle of Europe.

Electricity for the Central Pacific.

Electric locomotives for operating the mountain divisions of the Central Pacific Railway are said to be under consideration. It is believed that sufficient water power can be obtained from the mountain streams in the vicinity of the line to generate the current, and it is proposed to operate the road in this way from Sacramento east across the Sierra Nevadas to Verdi, Nev., a distance of 144 miles. While the above is only newspaper rumor, the high price of coal on the Central Pacific makes the story one which is not at all improbable.

NEW YORK NOTES.

MR. A. D. ISHAM, New York branch, 107 Liberty street, of the Eureka Tempered Copper Works, has been amusing his summer leisure by sending blotters to his friends. He says a prosperous season is at hand.

MR. G. A. NISBET, general manager of the Electric Appliance Co., Thomas Building, New York, has placed his Chicago agency in the hands of Mr. Martin J. Insull, who has recently opened up in that city as a manufacturers' agent. This agency includes the States of Illinois, Wisconsin, Michigan and Indiana.

STUCKY & HECK ELEC. MFG. CO., New Jersey Railroad avenue, Newark, N. J., are running their factory overtime and have been doing so for some weeks past, on all kinds of repair work.

EDMOND ELEC. TRACTION AND SIGNAL CO. has been formed with a subscribed capital of \$500 by D. N. Maxon, G. E. Cruse, C. S. Jones, D. A. Davies and R. H. Starr, all of New York City.

MANHATTAN RAILWAY CO. says it is still expecting to make the change to electricity, and that the matter will be put through as soon as possible after Mr. Gould's return this month, when, it is alleged a preliminary contract with the General Electric Co. will be put in execution.

PHILADELPHIA NOTES

THE ST. AGNES HOSPITAL, Philadelphia, will have an electric plant. The engines, which are to be built by the Ball Engine Co., Erie, Pa., are direct-connected to Eddy dynamos.

HUBBELL ELECTRIC LAMP CO., 1311 Capouse avenue, Scranton, Pa., are putting on the market a new electric lamp, chiefly for bicycle riders. The officers of the company are: Capt. C. J. Hubbell, president; Dr. L. M. Gates, vice-president; W. D. Boyer, secretary and treasurer. The company is reported as very busy.

HOT WEATHER has driven a good portion of the foreign population of Philadelphia into the rural suburbs, reached by trolley, where they spend the night in the woods in order to get sleep. Fox Chase is a favorite resort on account of its freedom from mosquitoes.

MR. T. B. DOOLITTLE has been awarded the Edward Longstreth medal of the Franklin Institute for his work in developing and securing the use of hand-drawn copper wire, of which such large use is now made, especially in telephony.

SOUTHERN NOTES

CENTRAL MANUFACTURING COMPANY, of Chattanooga, Tenn., are issuing a large postal card on which they enumerate a number of their excellent specialties in the electrical woodworking line, such as cross arms, pins, brackets, etc., with weights and prices in each case. They will be glad to receive inquiries as to line construction material.

CAROLINE LIGHT & POWER CO., Aiken, S. C., has recently ordered a 250 h. p. cross-compound engine from the Ball Engine Co., Erie, Pa. The engine is supplementary to their present power plant.

COLUMBUS, GA. The Columbus Power Co. is to develop electrically a water power of 40,000 h. p. President H. M. Comer, of the Central Railroad of Georgia, is at the head of the enterprise.

The Electrical Engineer.

Vol. XXVI.

SEPTEMBER 1, 1898.

No. 539.

The Mechanicville, N. Y., Three-Phase Transmission Plant.

INTRODUCTION.

THE development of the power of St. Anthony's Falls, on the Mississippi, at Minneapolis, Minn.,¹ is followed closely by the utilization of the power of the upper waters of the Hudson River at Mechanicville, N. Y., where an undertaking of no

power would without doubt find a market. But most important of all, it lay only seventeen miles from Schenectady, where, covering not less than 130 acres of ground, the largest electrical works in the world are operated from an extensive steam plant, with which the electrical power from the Mechanicville cataract could readily compete.

After consultation with the chief engineers of the General Electric Company, in which the necessary assurances were given, Mr. King formed the Hudson River Power Transmission Company. The hydraulic engineering features of the development were carried out in their entirety by Mr. A. C. Rice, chief engineer of the Stillwell-Bierce & Smith-Vaile Company, and it may be said that in the complete work as it stands to-day little or no departure from the plans laid down by Mr. Rice has been made. As the General Electric Company was to purchase the largest amount of power, its advice as to the electrical equipment was naturally closely followed. The result brought

THE POWER BEFORE DEVELOPMENT, MECHANICVILLE, N. Y.

less magnitude has, within the past few days, been completed. Five to seven thousand horse power is available at the power house and the use of high tension current permits of its distribution over a wide territory.

Early in 1897 the attention of Mr. R. N. King, president of the Stillwell-Bierce & Smith-Vaile Company, of Dayton, O., was drawn to this water power. His long experience with water

about by the harmonious co-operation of both hydraulic and electrical engineers is a power transmission plant in every respect strictly representative of the most modern hydraulic and electrical practice.

GENERAL LOCATION.

At the point chosen for the hydraulic development the physical conditions make the location an ideal place for a dam and

THE MAIN DAM AND WASTE GATES, MECHANICVILLE, N. Y.

powers and their development led him speedily to recognize the possibilities which here lay ready to hand. The site is only two miles from Mechanicville, eleven miles from Troy and eighteen miles from Albany, in each of which towns large quantities of

power house. The banks and bottom of the river are of rock, as is Bluff Island, which divides the Hudson into two channels, and here during the greater part of the year is water sufficient to produce from 7,000 to 10,000 h. p. The island is about one-third of the distance across the river from the western bank, the combined width of the two channels being about 1,200 feet. The

¹Electrical Engineer, June 2, 1897, and May 5, 1898.

western channel is used for the head and tail races. In order to make the excavations for the power house and the main dams heavy cofferdams were built across both streams.

DAMS.

The power house starts from and extends out into the river about 215 feet, and is connected with Bluff Island by a concrete dam 26 feet high above the bed of the river, 10 feet wide on top and 18 feet wide at the base. The up-stream face is vertical and

and pinion. The eastern dam is practically a solid rock wall capable of safely resisting any flood. To prevent any floating rubbish, ice or logs reaching the rocks or choking the waste-gates, a floating wooden boom stretches from the western end of the spillway diagonally for a distance of 400 feet to the edge of the normal river bank, and then for a distance of 1,000 feet to the main embankment of the Mechanicville highway. It is anchored to a line of stone-filled cribs. Between the west end

UP-STREAM SIDE OF POWER HOUSE, WITH FOREBAY, MECHANICVILLE, N. Y.

the down stream face sloping. The top of this dam is at an elevation that the water will never reach; thus, no provision is made to take care of falling water on the down-stream side, but the dam is provided with four arched waste-gates 4 feet wide and 6 feet 9 inches high, operated in the same manner as those in the main dam.

The main dam is on the eastern side of the island. It is built entirely of concrete, as indeed is the entire construction, with the exception of the upper walls of the power house. The up-stream face is vertical, the down-stream face is curved and provided with a horizontal apron 14 feet wide, which throws the falling water off horizontally, and thus effectually prevents wash

of the power house and the Mechanicville highway a broad roadway has been built of earth and slate rock.

To avoid any possibility of water finding its way through the embankment in case of very high water, a concrete core was put in the centre, starting at the solid rock and finishing two feet below the surface of the road. The embankment forming the roadway is 40 feet wide on the top, 124 feet at the base and 18 feet high at the deepest point.

THE POWER HOUSE.

The power house lies between the west bank and the short concrete dam, nearly filling the space between the island and the west bank of the river. It is practically a continuation of

PLAN OF POWER HOUSE, MECHANICVILLE, N. Y.

or scour of the toe of the dam. The dam is 16 feet high above the river bed, 8 feet thick immediately below the crest, 16 feet thick through the base and 30 feet thick through base and apron. The dam is set between massive abutments anchored to the rock sides of the river bank and island. The length of the spillway between abutments is 800 feet.

In the western abutment are twelve arched waste-gates of ample proportions. Each gate is 4 feet wide and 6 feet high, and is opened and closed by a heavy iron hoist operated by rack

the dam, and, like the main dam, is of concrete, with the exception of the upper walls. Its construction is of the most substantial character, the foundations are carried down to the bedrock and the house is carried on heavy steel box web girders resting upon steel I-beam columns. The latter are imbedded in concrete walls carrying arches, which form the floor of the generator room and the floor on which the wheel flumes rest. The walls form a separate and distinct tail race 22 feet wide for each set of turbines, from which the water may be shut out at will.

The house is divided into two parts by a thick head wall. The up-stream part contains wheel chambers for seven 1,000 h. p. wheels, of which five only are at present occupied. The down-stream portion contains the wheel governors and the electrical apparatus. The length of the power house proper is 257 feet 6 inches, the width of the dynamo room between head wall and

prevents the access to the wheels of any rubbish or floating material that may escape the boom.

MAIN WHEELS.

The main wheel plant consists of ten pair of 42-inch horizontal Victor turbines of the latest type, built by the Stillwell-Bierce & Smith-Vaile Company, of Dayton, O. Each main turbine con-

SIDE ELEVATION OF POWER HOUSE, MECHANICVILLE, N. Y., LOOKING UP-STREAM.

south wall, 34 feet, and the width of the wheel chamber portion 32 feet 6 inches. The total width of the power house is 66 feet 6 inches. At the western end an "L" extension runs up stream 87 feet 5 inches long and 44 feet 10 inches wide. This portion of the power house is of brick. A retaining wall runs down stream from the power house along the western bank a distance of 50 feet. The western stream, running between the bank and the island, forms the forebay, 300 feet long. The main tail race is 205 feet wide and joins the main stream 750 feet below the power house.

Arched chambers are provided for seven main wheels and two exciter wheels. Each main chamber is 32 feet 6 inches long, 22 feet wide and 17 feet 5 inches high, and is provided with two 6-foot manholes. Each exciter wheel chamber is 32 feet 6 inches long, 17 feet 5 inches high and 10 feet wide. The head wall of the chambers is 6 feet thick, the wall on the up-stream sides 3 feet thick. In the head wall of each main chamber is set a heavy cast-iron cover, through which the turbine shaft passes in a

sists of two pair of wheels, which, at the normal speed of 114 revolutions, is rated at 250 h. p. The total power of each set of turbines is, therefore, 1,000 h. p. Five units are now in position; the two additional turbines will be installed shortly. The head under which the water wheels are operated is 18 feet.

EXCITER WHEELS.

The turbines for the exciters consist of three 18-inch Victor cylinder gate wheels, having, at 259 revolutions per minute, a total of 300 h. p. The quarter turns and packing boxes of these wheels are brought through the wall beneath the station switch-board.

DRAFT TUBES.

Two draft tubes lead from each main turbine, the forward tube descending straight into the tail race beneath the power house, the rear or up-stream tube curving and flaring downward and outward. Each tube is 9 feet 6 inches in diameter at the bottom. Two draft tubes are also allotted to each set of exciter wheels, the setting following a similar arrangement. The rear tube is 4 feet in diameter, the forward tube, 3 feet.

MAIN AND EXCITER WHEEL GOVERNORS.

The speed of each set of main wheels is regulated by a Geisler electro-mechanical governor, mounted on a platform directly over the turbine shaft and between the head wall and the generator.

The use of electricity renders the mechanism of this governor

SECTION THROUGH EXCITER WHEEL CHAMBERS, MECHANICVILLE, N. Y.

watertight packing box, carrying the ring oil bearing for the shaft. The saving in space effected by the new arrangement of housing and coupling together of the turbines, patented by the Stillwell-Bierce & Smith-Vaile Company, has tended to diminish considerably the size of the power house. A 20-ton crane from the works of Pawling & Harnischfeger, Milwaukee, runs the entire length of the dynamo room.

In front of the wheel chambers and running the entire length of the power house is a trash rack of steel bars supported on a framework of steel channel and I-beams. This rack effectually

A MAIN WHEEL CHAMBER, MECHANICVILLE, N. Y.

extremely sensitive and effective, and the gates can be entirely opened or shut, should the full current be thrown on or off, in six seconds. The driving pulley is replaced by a rawhide pin-

ion, giving a rigid connection between the governor and the wheel, and making 400 revolutions per minute. The speed may be increased to shut off or throw on in less than six seconds if necessary. The Geisler governor is now in use in many of the most important electric power transmissions in this country and Canada, including those of Columbia, S. C.; Pelzer, N. C.; Lachine, Que.; West Kootenay, B. C., and Montmorency, Que.

The governors controlling the exciter wheel gates are improved "Snow" governors, which rapidly bring the speed to normal when changes are neither frequent nor heavy. They are especially adapted to the regulation of water wheels driving ex-

MAIN WHEEL GOVERNORS, GEISLER TYPE, MECHANICVILLE, N. Y.

citers, and are provided with adjustable stops, which limit the hoisting action on the gate as soon as the gate is fully open.

GENERATORS.

The dynamo room is a spacious chamber, well lighted by windows on all sides. It is 255 feet long and 34 feet wide, 30 feet 5 inches in the clear from floor to roof truss and 22 feet from floor to crane. The ultimate generator capacity of the station is 7,000 h. p. in seven generators, each of 750 kilowatts capacity. Five have been installed and are now running. They are unitooth, three phase, 40-pole 114-revolution alternating current machines, having revolving fields and stationary armatures, and wound to deliver 36 amperes of current at a periodicity of 38 cycles and a pressure of 12,000 volts to the transmission lines. They are arranged for operation in parallel at constant voltage. By using the revolving field type of generator and thus securing this pressure directly from the machine, the use of step-up transformers to raise the voltage for transmission purposes is avoided. As the current is to operate synchronous and induction motors, to operate lights and to be converted into direct current through rotary converters, a frequency of about 40 cycles was selected as most suitable for the different conditions required.

The alternators are similar in their main characteristics to those successfully used in the development of the power of the Lachine Rapids at Montreal.

The armature frame or ring is of the box type, 15 feet 4 inches in diameter and 36 inches wide. It is bolted to a base 18 feet 2 inches long by 10 feet wide, along which it may be moved parallel with the shaft, in order that the revolving field spider and poles may be uncovered should occasion arise. The armature winding is protected on each side by iron shields. The pillow blocks are also bolted to the base, and the bearings are of the spherical seated self-oiling type used in all General Electric generators.

The field ring is bolted to the spokes of the spider. It carries 40 poles, each securely fastened by two bolts to the ring. The whole revolves on a shaft 15 inches in diameter, provided with a rigid coupling on the turbine side bolted to a similar coupling on the turbine shaft. The dynamo shaft is extended for coupling to a vertical steam engine in case of necessity.

The following reasons for securing this type of alternator have been given by Mr. C. P. Steinmetz, of the General Electric Company: In addition to the advantage which the stationary

armature type has over the stationary field type in allowing a high transmission voltage to be taken directly from the armatures, it allows of a fairly low saturation of the magnetic circuit, giving an almost straight saturation curve. This is preferable in power transmission, since a considerable increase in the voltage may be obtained, if needed, to cover excessive drop in the lines due to heavy loads, and the voltage may be maintained even if the speed remains low.

EXCITERS.

The exciters are placed one on each side of the stairway leading to the switchboard gallery. They are 6-pole 100-kilowatt 125-volt standard General Electric machines, with ribbed field frame and ironclad armatures.

SWITCHBOARD.

The switchboard, erected on a gallery on the north wall of the dynamo room, is built up of nine highly polished panels of blue Vermont marble, each panel 7 feet 6 inches high, 3 feet 0 inches wide and 2 inches thick. Of these nine panels, five are used for the generators and two for the feeders; one is the total output panel and the last is for the control of the exciters. The generator panels occupy the left side of the board, and room on the gallery is left for two additional panels. The feeder panels are on the right side; the total output panel is between these and the generator panels, and the exciter panel is the third panel from the left-hand end of the board.

Each generator panel is equipped with the following instruments. One inclined coil alternating ammeter reading to 75 amperes for the generator and one direct current ammeter reading to 150 amperes for the field. Above each of these is a pilot lamp and between each pilot lamp a synchronizing lamp. Beneath the two ammeters is an inclined coil voltmeter reading to 15,000 volts, and beneath this instrument are three single-blade double-throw quick-break high tension switches, each mounted upon pyramids of corrugated hard rubber. Similar pyramids intervene at the back of the board, between the bus bars and the board. The corrugations give a total distance of about 8 inches of surface between the metal clips and hinge and the surface of the marble on each side.

As these switches are to break current of 12,000 volts, they are tested to break without difficulty currents of 21,000 volts. The switches are without handles. An eye is made in the end

750 K. W. G. E. THREE-PHASE ALTERNATOR, REVOLVING FIELD UNCOVERED, MECHANICVILLE, N. Y., TRANSMISSION.

of each blade, into which a hook at the end of a stick may be inserted and the switch opened by the attendant from a safe distance. Further, to prevent any dangerous arcing from blade to blade marble barriers $1\frac{1}{4}$ inches thick, 3 inches long and 12 inches wide from the face of the board are erected between each blade.

On the left-hand side of each generator panel sub-base are two 100-ampere double-pole double-throw carbon-break switches, one the field switch, the other the lighting switch. On the back of the panels are the high tension fuse blocks.

These fuse blocks, designed for 20,000 volts, are of the snap-break expulsion type. They are mounted on pyramids of corrugated hard rubber, which contain copper spring contact clips, between which two copper blades enter, connecting the fuse block to the line. The aluminum fuse is held tightly between two arms, which are moveable around a pivot, and may be pulled apart by two strong spiral springs encircling this pivot. As soon as an increase of current in the line melts the fuse its two halves are instantly pulled apart, and thus the formation of an arc between the two halves is prevented. The melting of the fuse can only occur in a small chamber protected by wooden blocks. The whole device is covered by two vertical wooden boards. Sliding in between these wooden boards in vertical slots are fibre shields intended to prevent arcing over between the two arms after the separation of the two halves of the melted fuse. The two wooden blocks and fibre shields are held in position by four screws. The whole fuse block is inserted in the line

These high potential plunger switches consist simply of long copper rods, sliding in hard rubber tubes. The upper ends of the rods reach into small rings, in contact with which they are held by a lever catching a small rubber band on the lower end of the copper rod. This lever is held in place by a spring and is released by moving a rocker arm on the back of the switch-board. The moment it is released a spiral spring pushes the copper rod downward, and by this movement, aided by the action of gravity, so suddenly is the contact broken that arcing between the rod and the ring is prevented. The rocker arm controls the three switches for each set of bus bars, so that they may be all released at once.

On the upper part of each feeder panel at the back is a current transformer for each outgoing line, two recording single-phase wattmeters, each reading to 25 amperes and 12,000 volts, and two potential transformers.

On the front of the output panel are two Thomson recording

INTERIOR OF POWER HOUSE AT MECHANICVILLE, N. Y.—DYNAMO ROOM.

simply by pushing the two blade-like copper contacts between the clip contacts, which are connected by solid copper rods to the bus bars. The wooden boards protecting the fuse are $10\frac{1}{2}$ inches long and $6\frac{3}{4}$ inches wide. The corrugated rubber pyramids on which the contacts are mounted are $3\frac{1}{2}$ inches high. The field rheostats are hung beneath the gallery and are operated by hand wheels on the gallery and bevel gears below it.

The exciter panel controlling the two direct current exciters carries two pilot lamps, two circular dial ammeters, each reading to 1,000 amperes, one volt meter reading to 150 volts, one four-point pressure switch, one synchronizing switch, two 800 ampere triple-blade double-throw equalization switches and two packed card rheostats.

The two feeder panels are similar to each other in every respect. Each outgoing line is provided with an independent ammeter reading to 150 amperes and a quick-break double-throw high-tension switch, similar to those on the generator panels, and similarly mounted on the board. Mounted also on corrugated hard rubber pyramids are the six circuit-breakers or automatic plunger switches.

wattmeters for balanced three-phase circuits, each reading to 300 amperes and 12,000 volts, and twelve triple-pole single-throw 100-ampere switches, with fuses for the lighting circuits. On the back are four potential and two current transformers.

The lightning arresters are of the G. E. short-gap type. The principle on which this arrester operates is very simple. It allows the passage of any high potential discharge, but effectually prevents the alternating current from following and maintaining an arc. The gap spaces in the lightning arresters at Mechanicville are very small—about 1-32 inch—each space lying between two solid metal cylinders 2 inches in diameter and 2 inches long. A low non-conductive graphite resistance is placed in the circuit, and the action of the arrester, therefore, is dependent upon the cooling effect of the large metal cylinders, aided by the reversal of the alternating current and the introduction of the non-inductive resistance. The line is protected by double-pole 2,000-volt arresters, connected six in series to give the necessary number of spark gaps. There are three sets of these. One at Mechanicville, grouped around the first transmission pole in a small house 15 feet square, one set on the Schenectady side of the

Glenville bridge, where the overhead pole line connects with the underground cable, and the third at the G. E. works.

LEADS.

The lead-covered leads from the generators are taken out at the base of the machine and are laid in ducts in the floor. Rubber-covered wire is used for the field connections. The cables rise on a frame from the duct to the floor of the gallery, through which they rise to the board. From the back of the board the line wires rise to supports bolted to the I-beam on the north wall, which supports one of the grand runways. The lines run along the north and west walls and pass out to the poles through a blind window over the door of the power house.

TRANSMISSION LINE TO SCHENECTADY.

The line from Mechanicville to Schenectady is the only one at present erected. It consists of three No. 000 B. & S. bare wires, this large gauge being employed in order to give the line as high self-induction as possible. This insertion of self-induction in transmission lines is a departure from earlier practice. In cases where synchronizing apparatus is used self-induction is now considered necessary and is artificially brought into the line in the shape of reactive coils in cases in which the natural self-induction is too small. The circuits are carried on poles 30 to 60 feet long and all 8 inches in diameter at the top. Each pole carries one cross-arm, on one side of which are two porcelain insulators of the triple petticoat type, a third being on the other side. For

EXCITERS AND SWITCHBOARD, MECHANICVILLE, N. Y.

lightning protection a barbed wire frequently grounded runs along the top of the pole line.

The line takes a westerly direction to East Glenville and then due south to Schenectady. At the end of the Glenville bridge over the Mohawk, the town limits, it is carried down to the ground and connected to three cables of No. 1 gauge stranded copper insulated by $\frac{1}{4}$ inch rubber and 3-32 lead sheet, laid in terra cotta conduits. These cables run seventeen hundred feet along Washington avenue, rise to poles again through Rotterdam street to the Erie Canal, and along the canal to a point directly opposite the General Electric Company's power station. They then cross the canal and enter the works.

THE UTILIZATION OF THE CURRENT AT THE GENERAL ELECTRIC COMPANY'S WORKS.

The introduction of this transmitted electrical power into the factory will work a considerable change. At present all the machinery is driven by electric motors, while the testing department demands an independent supply of current for the work it carries on. There are at present, therefore, two distinct generating plants. The 550-volt motors in the testing department are supplied from an engine-driven multipolar generator of 500 kilowatts capacity, while a smaller engine drives a number of exciters, which allow of independent control of the excitation of all machines in this department. The factory is operated by a number of 250-volt motors, running on the same circuit as the factory lights. These motors will not be changed, and the steam plant which supplies them will be retained as a reserve in case the power from Mechanicville should fail. The electric power plant superseding the present steam plant at the works will, therefore,

consist of two synchronous motors, one of 500 kilowatts, the other of 100-kilowatts, and three 400-kilowatt rotary converters—the synchronous motors for the testing department, and the converters to supply current to the factory motors.

The large engine driving the 500-kilowatt multipolar generator is superseded by the 500-kilowatt synchronous motor. This is a 12-pole 400-revolution machine of the revolving field type, wound directly for 10,000 volts. The small engine driving the exciters is replaced by the 100-kilowatt synchronous motor—an 8-pole 600 r. p. m. revolving field machine similarly wound. This disposition renders this department independent of everything, the speed of the Mechanicville generators being kept as nearly as possible constant.

The three rotaries supplying 250-volt current to the factory motors are 10-pole 400-kilowatt 480 r. p. m. machines, having two commutators and two sets of collector rings, connected to independent windings on the armature. They receive the three-phase current from independent secondary coils of the same set of air-blast transformers. When connected in multiple they furnish current at normal pressure of 250 volts, but as they may be called upon to furnish current to the testing department in case the demand exceeds the supply from the synchronous motor-driven machine, they may be connected in series to give 500-volt current, operating in parallel with the railway generator driven by the synchronous motors in the testing department.

The rotaries are operated in parallel, and all the factory motors, the factory railway and all the factory lighting are operated from the same direct current circuit, the latter on the Edison three-wire system, the neutral wire of the three-wire system being secured by connecting the transformers for the rotaries in Y with their secondaries and bringing to the neutral a lead from their common connection.

Synchronous motors were selected in preference to induction motors on account, first, of their more constant speed and greater efficiency; second, because they do not produce lagging currents, but the phase displacement and power factor may be controlled as desired by means of control of the field excitation.

Synchronous motors of the revolving field type and of good design are self-starting even under heavy load, and will easily carry two or three times full load without falling out of step for a time, limited only by the heating of the motor.

To make the entire system at the G. E. works self-regulating in the direct current distribution and as far as possible independent of hand regulation, the rotary converters are given shunt field and powerful series field, so joined together that the machines operate as one unit. With constant voltage in the generating station at no load, the counter e. m. f. of the rotaries, as given by their shunt field is below the impressed e. m. f., and a lagging current is produced. The self-induction of the lines is thus in opposition to the voltage, which is so reduced as to give 250 volts at the commutator brushes of the rotaries. As the load increases the counter e. m. f. of the rotaries rises, due to the series field, until at full and overload it is greater than the impressed e. m. f., and the current becomes leading. The e. m. f. of self-induction of the lines is then brought partly in phase with the voltage, which is increased so that, in spite of the increased line current and consequently increased energy loss in the line, with constant generator voltage, the same voltage is produced at the commutator brushes of the rotaries at no load as at full and overload. This control is, therefore, automatic in every way, and did the synchronous motor not take current over the same line in varying quantities, would suffice. To render this control perfectly automatic, therefore, small series transformers are inserted in the lines leading to the synchronous motors, feeding a small synchronous motor generator controlling the shunt field of the rotaries. By the combined action of their shunt and series fields the voltage is automatically maintained constant at the commutator brushes of the rotaries, and no hand regulation is required beyond that of readjustment in case the number of rotaries in operation is changed.

The entire construction of the dams, power house and lines has been carried out with the highest engineering skill by the National Contracting Company, of which G. H. Furman is general manager; E. A. Mathews, superintendent, and J. A. Leonard, constructing engineer. The electrical equipment is furnished by the General Electric Company, and the hydraulic equipment by the Stillwell-Bierce & Smith-Vaile Company, of Dayton, O., to which company was confided the entire development contract. It took the Hudson River in its natural condi-

tion and turned over to the operating company the plant in running order.

The officers of the Hudson River Power Transmission Company are: General Edmund Hayes, of Buffalo, N. Y., president; R. N. King, president of Stillwell-Bierce & Smith-Vaile Company, of Dayton, O., vice-president; G. M. Furman, Newark, N. J., treasurer; Mr. E. J. Richards, Boston, Mass., secretary; Mr. J. S. O'Shea, superintendent.

Long Distance Transmission of Power.¹

BY ERNST J. BERG.

CONSIDERING that this paper is read before an Electric Lighting Association, the greater part will be devoted to power transmission for lighting and lighting with incidental motor load. When, in the early '90s, multiphase systems were introduced on a commercial scale, it looked as if the field for the simple single-phase system would be limited; indeed, as if it should be altogether superseded by the new system, yet upon investigation of all properties of the latter it was soon apparent that, although the multiphase systems were superior for some conditions, such as for operation of motors, they could not favorably be compared with the simple alternating current system for lighting. Yet, although this was known and appreciated, already in the early days mistakes have often been made in choosing the best system when contemplating a new installation. The reason for this mistake lies probably in the fact that it is generally assumed that alternating current motors must run on multiphase circuits, and therefore, even if the motor load does not amount to anything, when installing a new plant such a system has been adopted.

Except for very long-distance transmission, as will be discussed later, multiphase systems are really only excusable where power is generated a long distance from its distribution points, and there supplied in a low tension direct current network by means of rotary converters.

At the present stage of the art there can be no question but that every central station man sees the advantages of parallel operation. With this is meant not only parallel running of generators in the station, but also multipole connection of the distribution system, be this direct or alternating current. This feature is most important, as well for economy as for satisfactory operation. From the nature of things it is evident that such distribution system could not be laid out multiphase; therefore, when alternating current is used, single phase should be adopted.

Against this argument it is often stated that in a territory where the load is scattered greatly a secondary network cannot be well laid out, but each customer or set of customers has to be supplied from his own transformer, in which case the distribution is single phase, regardless of whether the system is single phase or multiphase. If a multiphase system is used, single phase mains are brought over to the individual customer or groups of customers. This arrangement may look feasible on paper, particularly so if no investigations are made to determine the potential in these single phase mains.

By a few calculations, however, it is readily found that, although apparently everything is nicely balanced, such system is very often much unbalanced and consequently perfectly unsuited for its purpose. But even were it possible to distribute from a multiphase system with scattered transformers on each main, it is not at all correct to install such a plant, because any well-managed power distribution must some time increase in magnitude, and arrangements should be made so that it can be changed over to a perfect system when need be, which is only possible where each circuit has the same phase; that is, this is only possible with the single-phase distribution from a single-phase generator.

A still further reason for not adopting the multiphase system is that at the present time motors can be operated perfectly satisfactorily from a single phase system; that is, single phase system such as the monocyclic system.

As referred to above, there may, however, be conditions which would warrant a multiphase, or rather, a three-phase, installation, and these are when the distances between generating station and consuming circuit are so great that power cannot be transmitted from one to the other except at the highest possible commercial voltage without too great an expenditure of line copper. Under such conditions the three-phase system, which takes

75 per cent. of the single-phase or two-phase copper, and say about one-half as much copper as the monocyclic system, may be preferable. For shorter distances, however, where it is not necessary to run at the limit of permissible voltage, the apparent saving in copper in the three-phase system over the monocyclic system is of little consequence, since the monocyclic system can be operated with the same amount of copper at a slightly higher voltage. Thus, excepting very long-distance transmissions, the only field for multiphase system is in places where installation of rotary converters are warranted.

The next question of interest is the determination of proper frequency. The 60-cycles or 125-cycles lighting distributions are certainly preferable to the 25 and 40-cycles distributions; indeed, there can be hardly any question of installing anything less than 40 cycles, and such a low frequency can only be warranted by limitations in speed regulation of the prime mover. The tendency seems not to be to have direct connected units as far as possible. Without arguing about this point, it seems that this is correct in most cases, yet undoubtedly it is carried too far in many instances. With very large units such as 1,000 h. p. and more there is no doubt but what the direct connection is better, but we often face propositions where the customer wants to install direct connected slow speed 75 to 100-kilowatt machines. That is, in my opinion, to carry things a little too far, since the slow speed necessitates very large and efficient alternators, with very many poles and engines with exceedingly close speed regulation.

In order to obtain satisfactory parallel operation of alternators, it is necessary that their speed be uniform, and since no steam engine of reciprocating type can be made which gives a perfectly uniform rate of rotation, it is necessary to advise in some cases generators which are most suitable for the engines. It is often possible to build a 25-cycle direct connected alternator which will operate perfectly satisfactorily from a given steam engine, whereas if a 60-cycle alternator were installed on the same engine, its behavior would be so bad as to make parallel running prohibitive.

The amount of permissible variation is indirectly proportional to the frequency of the alternator connected to the engine, so that, for instance, if a 20-pole alternator was directly connected to a steam engine which gives a speed variation of, say, $\frac{1}{2}$ per cent., and it was desired to get as satisfactory results with a 40-pole alternator, that is, with an alternator giving double frequency, it should be necessary to have $\frac{1}{4}$ per cent. speed variations.

If belted alternators are used, it is hardly ever necessary to consider lower frequencies than 60 cycles, since the question of speed variation of the engine is, of course, not of such importance as with the direct connected engine, yet it may be given as a rule that cross compound engines should be used wherever possible.

Since incandescent lighting and arc lighting are unsatisfactory for frequencies below 60 cycles, it is evident that we always have to consider either 40, 60 or 125-cycle systems, these being the standard frequencies, and of these the 125 or 60-cycle system should preferably be used, and the 40-cycle only when forced by the speed regulation of the engine.

Regarding the preference of 125 and 60 cycles, it is hard to give any rule. Were it not for the higher speed of the 125-cycle alternators, I believe I favor them, particularly so if the distance of transmission is not too long so that the line inductance may be objectionable, and if the secondary network is not too expensive and too large conductors used. Yet if there is a probability of considerable motor load 60 cycles may be better. In connection with this it may be well to bring out the fact that 125-cycle ironclad alternators are very well suited for parallel operation. Thus, a rule regarding frequencies may be to use as high frequency as possible and where no limitations are imposed by the driving power, use nothing lower than 60 cycles.

With rotary converter installations, the question of frequency is different. There the intention is not to distribute from the multiphase alternating circuit, but only through a direct current network. The frequency of such a system is preferably 25 cycles, since at this frequency the regulation of the engine need not be so extremely good, and the rotaries can be built with relatively slow speed. The three-phase system is, of course, preferable to the two-phase system, since it requires less copper, less lines, less switching arrangements, etc.

¹Read before the Ohio Electric Light Association.

Sometimes, however, it is very desirable to distribute the greater part of the load by means of the rotary converter direct current network, but also to do some lighting in another territory. Under such conditions, it is rather attractive to install a 60-cycle three-phase plant and use 60-cycle rotary converters, in which case the lighting could be directly done from the 60-cycle mains.

Considering, however, the high speed which is necessary in connection with the 60-cycle rotary converter and also the extremely close speed regulation of the engine or turbine driving the alternator, it may not always be a good policy to use them, but would recommend the installation of a frequency changer in connection with the three-phase 25 cycle alternating current generator.

Such frequency changer can be used for transforming three-phase power to single-phase power, 25 cycles to 60 cycles, and any impressed voltage to another. So, for instance, with the frequency changer installed in Brooklyn, power is transformed from 6,600 volts three-phase at 25 cycles to 2,600 volts two-phase power at 62 cycles. This frequency changer is to all appearance an induction motor driven by a synchronous motor. Its capacity is less than the capacity of a corresponding motor generator set and its efficiency is higher.

Finally, regarding the low potential alternating or direct current network from rotary converters, there need hardly be any discussion, since every central station man is fully familiar with the present methods of distributing for lighting.

Aerial Construction of Fire and Police Telegraph Lines.¹

BY WILLIAM H. THOMPSON,

Superintendent Fire Alarm and Police Telegraph, Richmond, Va.

OF course the telegraph construction would largely depend upon the service we wish to provide for, and just here I will state that my ideal of a well organized fire and police department is one with a perfect water supply, good apparatus and men, and officered by men of cool judgment and tried bravery, each department of which is run on its merits, solely independent of outside influences with all parties in its favor, and politics out of the question entirely. The importance of the electrical part of these departments cannot be overestimated; that is, where the telegraph and telephones are used.

I know of no better way of illustrating the importance of the fire and police telegraph than to compare it to the commercial telegraph of this age, which pins the whole world together and over which we may send a message and receive an answer from the other side of the world within the time occupied in writing this.

If it is true that "the press is the lever that moves the world," it is no less true that the press is almost entirely dependent upon the commercial telegraph for this power. It is also true of all railroads; in fact, in time of peace or in time of war the telegraph is invaluable.

The best system is none too good for the fire alarm and police telegraph service, and the construction must of necessity be the best, whether aerial or underground. In my opinion, underground is the proper place for these important wires from which so much is expected. However, in cities where limited appropriations will not admit of underground work, and where the superintendents are compelled to maintain their systems overhead among thousands of foreign wires, crossing and recrossing the city wires, I am of the opinion that if in their cities there is no regularly employed city electrician, the superintendent of the fire alarm should, by virtue of his office, have charge, and it should be made his duty to see that no wire, pole or fixture is erected without his knowledge.

What difference does it make if Mr. Jones cannot talk to Mr. Smith over his telephone wire? But let Mr. Jones pull the lever in the fire alarm or police telegraph box, and he fails to

get the officers and apparatus until smoke and light or a messenger directs the firemen or police to the scene possibly too late to save valuable property and sometimes life, and the public would soon let you know the difference between the telephone, electric light or power wires, and those of the fire alarm and police telegraph.

There are so many details entering into the calculation of overhead construction that it is almost impossible to lay down any fixed rules for them. There is always present the danger of the fire alarm and police wires getting afoul of high tension wires, causing instruments and fuses to be burnt out at the very time they are most needed.

Another important point of overhead construction is to so construct the line that in case of fire the wires will be as little in the way of the firemen as possible, and also to give these brave men some knowledge of what some of these innocent little wires will do in case of contact with them.

Now that the electric light and power wires, although of a comparatively recent birth, are public necessities and opposition telephone companies are springing up all over the country, in most cases doubling the number of wires we have to contend with, and as the fire departments deal directly with these wires, I see nothing else to do than to advocate the underground system.

Telegraph Revenue Tax Fight in Kansas.

The Atchison, Topeka and Santa Fé Railway Co. has begun a suit in the Federal Court at Topeka, Kan., to compel the Western Union Telegraph Co. to pay the revenue stamp tax on telegrams filed by the railway company. The proceeding is in the form of an injunction to prevent the telegraph company from refusing to accept for transmission messages without the revenue stamps attached. The complaint alleges that the telegraph company violates its contract with the Santa Fé company when it refuses to accept unstamped messages for transmission. The contract in question gives the railroad company reduced rates and free transmission under certain conditions.

Electricity in Engineering Courses Other Than Electrical.¹

BY PROF. J. P. JACKSON.

THE present extended use of electricity in industrial undertakings has made a knowledge of its control indispensable to the well rounded engineer.

College courses preparing for the older engineering professions were established while electricity was of small service. Through human inertia these courses have tended to continue on their old lines. The present time, therefore, finds training in electricity far from satisfactory in engineering courses other than electrical.

The work usually assigned is the electricity and magnetism of the general college physics course, with possibly one term on its applications. No time is given to a vigorous advanced treatment of the subject from an engineering standpoint. The college physics course might as well be depended upon to give the requisite training in applied mechanics or thermodynamics.

In addition to the work now usually scheduled, a thorough training in the laws of direct and alternating currents, as they apply to the practical utilization of electricity, should be added. This should be taught by an engineer, and should be assigned time comparable to that given the steam engine, hydraulics and hydraulic machinery, etc. This time could be obtained with advantage by cutting out special work. An outline of such a course is included in this paper.

As scientific knowledge increases, engineering courses must give more time to fundamental principles at the expense of mere technical practice. Hence such courses tend to converge.

If electrical engineering studies are to be satisfactory they must be under the supervision of an engineering department,

¹Abstract of paper read at Municipal Electricians' Convention, Elmira, N. Y.

¹Abstract of paper read at the sixth annual meeting of the Society for the Promotion of Engineering Education, Boston, Mass., August, 1896.

and should not be taught by instructors in the departments of physics.

Electric Lighting at the Pitman Grove Camp Meeting.

BY BINGHAM HOOD.

THE meeting ground of the New Jersey Methodist Conference, located at Pitman Station, on the West Jersey Railroad, sixteen miles south of Camden, N. J., is visited annually by thousands of persons from all points in the Eastern States.

The grounds, heretofore, have been lighted by oil lamps of the old-fashioned kind, often seen in rural districts. At the commencement of the present season the directors decided to adopt a more modern form of illuminant, and accordingly made a contract with the Gloucester County Electric Company to light the entire grounds with incandescent lights, spaced one hundred feet apart on the main avenues, and one hundred and fifty feet on the less prominent streets. All the lamps to be of thirty-two candle power.

The property is thickly covered with large chestnut, oak, and pine trees, ranging from six inches to five feet at the butt, and

Outside of this wheel is the larger part of the ground, to light which, without using a large number of transformers, or heavy secondary wires, presented the most difficulties.

It was finally decided to, figuratively speaking, take the bull by the horns and adapt a different system, the one finally fixed upon being a series incandescent system, but differing from any other in having no street fixtures, shunt boxes or other cut-outs.

To describe this system is the main object of this paper, as the same system can be used in many places where the income would not be sufficient to pay for shunt boxes or other fixtures.

Starting at a centre, each circuit passes through a telltale and switch, which will be described later. From this the wire goes to the first lamp; the circuit being here broken by introducing a common porcelain knob, such as is used in all line work; one end of the wire passing around the groove and twisted, the other end going through the screw hole and twisted. (See Fig. 1.) Across this insulator is bridged a weatherproof socket and lamp; the joints being left bare, the purpose of which will be described later. The wire then follows in the same way from lamp to lamp, as in all series systems, until ten lamps are on each circuit.

The primary voltage is 1,080, each lamp being 106 volts special series burning railway pattern. This leaves 20 volts for the line loss, each circuit being about 4,000 feet long and of No. 10 wire.

At the beginning of each circuit is a cut-out box, containing a plain porcelain receptacle, in which is a short circuited attachment plug, acting as a switch; and a solenoid coil. The core of this coil fits loosely and upon being raised by the current, separates a pair of contacts, opening a secondary circuit, fed

FIG. 1.

FIG. 2.

CAMP LIGHTING WITH SERIES INCANDESCENT LAMPS.

FIG. 3.

planted so thickly that it was impossible to find a stretch clear enough to run from pole to pole, and the association objected to the use of poles at any point, unless they were of iron.

As the contract is only for three months in the year, it was out of the question to go to this expense, and it was decided to make use of what at first promised to make trouble, namely, the trees; and the work was all done by bracketing to these, the wires not being stretched, so that the swaying of the trees does not place any extra strain on the spans. The system has been in service over two months and only one broken wire has resulted, this being caused by a poor factory joint.

The entire job has required about fourteen miles of wire, ranging in size from No. 6 to No. 10 B. & S. gauge; to support this has required over three thousand brackets and insulators, making probably the largest bracketed electric lighting installation in the country.

The fixtures are the simplest, cheapest, and probably the safest that could well be gotten, being nothing but standard porcelain weatherproof sockets, supported directly on the span.

The main part of the grove is laid out like a wheel, with twelve spokes; the hub being the Auditorium, or main meeting building, around which is a circular avenue; radiating from this are twelve avenues, each leading to the outer circle. The avenues and the buildings on them are lighted by a three-wire 208 volt system, supplied from a large General Electric converter at the centre.

from the large transformer spoken of before, and supplying a 10 candle power red lamp. See Fig. 2.

The inspector has only to look at these indicators to see if each circuit is burning. If the signal lamp is burning a circuit is open, the trouble being usually a burnt-out or stolen lamp. He starts over the circuit provided with a short-circuiting hook, consisting of two insulating sticks, on each of which is fastened a hook made of No. 6 wire; bridged across these sticks is a piece of flexible cord and a socket and lamp (see Fig. 3). By placing one hook on each joint, where the socket is connected, the lamp between the hooks will light when the bad lamp is reached, and is then easily repaired.

The only trouble arising from this system has been that when a lamp burns out it will generally explode, creating an arc, which follows up through the lamp base and socket, destroying the socket. This, however, is a small expense, as a new socket and lamp only means an expense of forty-one cents.

These circuits have been burning a total of over four hundred hours, and only three lamps have been burned out, out of a total of 160. The average cost of erection has been but three dollars and sixty cents per lamp, against twenty dollars for the standard series system, and has given equally as good service. Of course a system of this kind would hardly answer where the service is the year around, but for a summer service is without an equal, considering the low first cost and small repair account.

[Entered as second-class matter at the New York Post Office, April 3, 1898.]

Vol. XXVI. NEW YORK, SEPTEMBER 1, 1898. No. 539.

Novel and Extending Uses of the Storage Battery.

AN answer similar to that of Benjamin Franklin to the question "What is the value of a child?" that "It will some day become a man," was singularly applicable a few years ago to the query as to the use of the storage battery. And the infant of that time has certainly not disappointed us, as evidenced by its wonderful development and rapid growth during the last four years, when the total weight of plates installed has increased tenfold, while the weight and cost of each individual cell have been materially reduced. The web of litigation has fortunately been swept away, the correct use of the battery has been discovered and new fields of usefulness have been opened for it.

In discussing the recent developments in the applications of storage batteries before the Engineers' Club of Philadelphia, Mr. Joseph Appleton made the significant statement that the installation by the Chicago Edison Company of a storage battery, the plates of which weigh over a million pounds, capable of delivering 2,000 horse power for one hour, has conclusively shown that "the storage battery of to-day is not an experiment or a toy, but a piece of apparatus constructed on proper mechanical, electrical and chemical lines, and one which is as much of a factor in the generation and distribution of electrical energy as boiler, engine and dynamo."

As one of the most important of recent applications of the storage battery is mentioned, its connection with the development of water powers for the generation, transmission and distribution of electrical energy for power, lighting and manufacturing purposes. This is illustrated by the installation of a very interesting plant lately by the Buffalo Street Railway Company, as described in these pages, operated in connection with a booster which compounds it to any desired extent. The aim, of course, is to keep the rotary converters as fully loaded as possible, in order to get the greatest benefit from the Niagara Falls power.

The advantages of the use of storage batteries for elevator service are too evident to require any argument and are admirably summed up by Mr. Appleton as follows: "Smaller generating plant necessary; only one unit need be run, instead of two, with consequent saving in labor; greater economy of operation, due to plant being run at a constant and efficient load, instead of a varying one; smaller depreciation on plant, due to entire absence of heavy loads being suddenly thrown on the same; greater reliability on account of battery being ready to take entire load in case of emergency."

Another recent and widely different use of the storage battery is its employment in telephone exchanges, where they are centralized to replace the batteries formerly installed with each subscriber's instrument. While this application is not yet uni-

versal or widespread, the opinion has been expressed by well known telephone engineers that the time is not far distant when the value of the storage battery for the above purpose will be generally recognized by every telephone exchange manager in the country.

By far the most extensive and interesting use of the storage battery in recent years, however, and one for which there seems to be a limitless field in the near future, is the furnishing of power to electric vehicles. It has been shown by recent trials and developments that electricity is the ideal agent for carriage propulsion, having the following advantages over the use of any oil or gas: It is safe; can be easily handled and controlled; the electric motor makes less noise and creates less vibration than oil or gas motors; the absence of heat and smell, and its small cost of operation. Besides these the electric current possesses other advantages which might be mentioned to show its superiority, but the above will suffice in view of the fact that as a motive power for horseless vehicles it has already taken the lead. Thus we see a new and vast field opened for the storage battery which is being exploited to its fullest extent in America where we are making up rapidly for our reticence in the past. No better evidence of this can be found than in the splendid equipment of the charging station of the Electric Vehicle Company, of New York, described on other pages in this issue, and the increasing demand for electric vehicles in that and other American cities. The new use means additional employment for the electric current, and the Edison Company of New York are planning to provide charging plugs in the streets all over the city, so that, if necessary, a cab can pull alongside a charging plug and fill up. It will besides, impart a boom to the carriage tire and other industries, and above all, it will probably have the much desired effect of giving us a low cost, highly efficient and light-weight storage battery.

The Limitations of Power Transmission.

WE have before us a catalogue of one of the best known electric manufacturing companies in the country, in which are enumerated plants, with detailed data, aggregating a combined capacity of one-quarter of a million horse power of poly-phase electric transmission apparatus. By far the largest percentage of this work is carried out with the aid of water power as the initial source of energy. The unabated increase in the utilization of such powers both here and abroad made possible by the aid of electrical transmission ought to be sufficient evidence of the financial success achieved by such plants in the past, and it is safe to say that no halt will be called in the march of progress begun so auspiciously. It is hardly to be expected that every enterprise of this kind should have proved an unqualified success, but we can look with complacency on the few instances in which trouble has been experienced, and we do this in the belief that by pointing out the mistakes that have been made a service will be rendered to those who are now operating or who contemplate the installation of water power transmission plants.

The few instances referred to may be simmered down to two general causes, namely, that some companies have "bitten off more than they can chew," while others have suffered from bad initial engineering, or again, from both causes combined. For instance, we know of a case in the East where a company during the past month was unable to maintain the normal candle power of its lamps owing to the severe drought and a defective dam. Another case is that of the Redlands Electric Light and Power Company, California, which claims attention on account of the prominence of the plant. This company, it seems had contracted to furnish the city of Riverside, Cal., with 200 h. p. The company has not been able to do this of late, and the city authorities have notified the company that the city is suffering great damage and loss from the lack of power, and will hold the company responsible. They even speak of forfeiting the \$15,000 bond of the company. Here again the trouble is due to the lack of water in the mountains. But what will be more a matter of general surprise is the rumor that the Folsom-Sacramento power transmission plant is to be supplemented by a steam plant in order to carry the load.

These three examples, we believe, can all be included under the causes given above. The first duty of every company distributing electric power, for whatever purpose intended, is to provide for uninterrupted service. Without this no customer will be satisfied, and without satisfied customers there can be no

progress from a financial standpoint. It does not by any means follow that every water power can be successfully transmitted to long distances. The conditions which determine success, however, can in every case be fairly well prognosticated, but such prognostication ought to be left in the hands of most competent engineers. Nor does it follow that a water power transmission is subject to any other general laws as to loading than is a steam power plant. In fact, the advantage, if any, is on the side of the latter, for whereas a steam plant can, in case of emergency, be forced considerably beyond its normal capacity for extended periods of time, such is not the case with a water power plant. It follows, therefore, that to load up a water power plant beyond its capacity is a practice which will sooner or later bring on trouble. All these troubles, however, can be avoided by judicious management, and the examples we have cited above seem to us merely to indicate that had due precautions been taken the unfavorable results experienced could have been avoided. Certain it is that the art of electric power transmission is now so well established and its limitations so thoroughly understood that there can be no excuse for failure in the future.

Municipal Ownership Agitation and Its Antidote.

IN a recent issue we had occasion to dwell on the report of the Detroit municipal electric lighting commission, an analysis of which showed that even that much-vaunted example of municipal ownership could hardly be said to have fulfilled the expectations of its projectors. Indeed the commission acknowledged as much in its report. While the agitation for municipal proprietorship is still raging, we believe that the evidence now rapidly accumulating is beginning to have a salutary effect, and where precipitancy was formerly the rule, a conservative hesitancy is now observable on the part of many communities. The agitation being still alive, however, it is well to guard against its prime cause, and that is, it seems to us, bad service on the part of the electric lighting companies. A flood of light is thrown on this phase of the subject in the paper of E. P. Roberts, read before the Ohio Electric Light Association. Mr. Roberts having acted on behalf of several municipalities in their disputes with private lighting companies, speaks by the card. What did he find? In most cases the companies were furnishing a good commercial article, so to speak, and living up to the spirit of the contract. In other cases, the contrary fact was noted. Sometimes considerable indignation was expressed at preliminary information obtained by him without having notified the lighting company that he was in town, and the greatest objection was made by the president of the company giving the poorest service! Where the company was living up to its contract, the result of Mr. Roberts' investigation resulted in a much better feeling toward the company on the part of the municipal lighting committees, and the agitators against the local companies were practically disarmed. The history of human error finds constant repetition in spite of that history. The proverbial leniency and even indifference of the American citizen to public abuses have their limits, and what would be tolerated indefinitely in some cases will in others arouse speedy resentment. Street illumination is among the latter. The average citizen will worry along with dirty streets and bad water for a lifetime, but when it comes to street lighting he demands his money's worth or wants to know the reason why. We hope the lesson embodied in Mr. Roberts' paper will not be lost. There are many companies who have long since learned that a permanent and prosperous business can only be built up by fair dealing with the public, but there are still some who apparently have not yet learned that lesson.

The New Element, Etherion.

THOUGH Mr. Charles F. Brush has for quite an extended period abandoned the field of electrical invention, he has of late devoted himself to other lines of research, and some of the results of his work are embodied in a paper presented by him before the American Association for the Advancement of Science at its meeting in Boston last week. In that paper Mr. Brush describes the properties of a remarkable gas discovered by him and which he has named "etherion." The properties of this gas are described in Mr. Brush's paper, printed elsewhere on this page, and, as will be noted, Mr. Brush hazards the conjecture that possibly etherion may be found to be identical with the so-called ether. No doubt some similarity will be found, because

even ordinary gases correspond to some of the properties of the ether, but we imagine that the crucial test of this new gas will show it to lack one essential characteristic of the ether, and that is high elasticity. But even without the hope of identifying etherion and its co-ordinate gases with the ether, the new discovery in itself is one of unquestioned interest and importance.

Single Phase and Multiphase Motors on Lighting Circuits.

THERE are to-day many central station managers who see the necessity of extending their facilities to meet the demands of their customers for electric power, but who are in a quandary as to just what system to adopt, taking into consideration all conditions. It is one phase of this problem that Mr. E. J. Berg discusses in his paper read before the Ohio Electric Light Association, which will be found elsewhere in this issue. In order that our readers may not draw false conclusions from Mr. Berg's statements, it may be well to point out that he limits the problem under discussion to power transmission for lighting and lighting with incidental motor load; hence, the paper does not refer to conditions where motor load is of first importance.

Etherion.¹

BY CHARLES F. BRUSH.

THE gas is a constituent of the atmosphere and is found absorbed in many substances. Its chief characteristic thus far experimentally determined is enormous heat conductivity at low pressure. Mr. Brush showed that its conductivity even when mixed with a large excess of other gases is something like a hundred times that of hydrogen, the best gaseous conductor heretofore known; and conjectures that the conductivity of the pure gas will be found a thousand or more times that of hydrogen. He discovered the gas nearly a year and a half ago, while looking for occluded hydrogen in glass. He found not only hydrogen, but something of vastly greater importance. After many months of experiment he has recently effected partial separation of the new gas from the air by diffusion. In the first diffusion the heat conductivity of air was increased something like a hundredfold. Mr. Brush expects to obtain the gas in a state of approximate purity by successive diffusions of air.

A table of figures was exhibited, showing the molecular weight, density, specific heat, relative mean molecular velocity, and heat conductivity of the gases whose heat-conducting curves appeared in the chart; and attention was directed to the evident close relationship between the heat-conductivity and molecular velocity of the gases. From this relationship some other properties of the new gas were deduced. Taking the heat conductivity of the new gas at a hundred times that of hydrogen, a very conservative estimate, its mean molecular velocity at freezing temperature was calculated to be more than a hundred miles per second, and its density only a thousandth part that of hydrogen; while the specific heat was found to be 6,000 times greater than that of hydrogen, the substance having the greatest specific heat heretofore known.

It was shown that a gas having attributes anything like those cited could not possibly be confined to the earth's atmosphere; and hence the new gas, being found here, probably extends indefinitely into space and constitutes an interstellar atmosphere. In recognition of this probability Mr. Brush has named the new gas etherion, meaning "high in the heavens."

Some evidence was cited tending to show that etherion is a mixture of at least two different gases; and Mr. Brush hazarded the conjecture that on further investigation three or more gases will be found, forming one or more periodic groups of new elements all very much lighter than hydrogen. The possibility that etherion may be found to be identical with the so-called ether was touched upon, and Mr. Brush expressed the hope that it would be found to account for at least some of the phenomena heretofore attributed to the ether.

¹Read before the A. A. A. S. Abstract.

The Cabs and Central Station of the Electric Vehicle Company of New York.

OF all the recent applications of electricity, there is perhaps none which exceeds in interest nor one which offers greater possibilities for future expansion than that of electric vehicles. The progress made in this art abroad within recent years has acted as an incentive on this side of the Atlantic, and the work accomplished in the United States in the brief space of a few years has been most remarkable and encouraging. Not alone have the types of American horseless vehicles eclipsed their European prototypes, but every detail has received the stamp of American ingenuity and foresight. In recent issues we have described the products of several American and foreign manufacturers, which

in other words, a spot centrally situated on the Island of Manhattan within easy reach of the majority of theatres and not too far distant from the business and residence portions, as well as railroad stations and ferries.

Such a place was found at Broadway, between Fifty-second and Fifty-third streets, extending through to Seventh avenue, which was formerly used for a skating rink and bicycle academy. This building, which is shown among the accompanying illustrations, is about 200 feet long and has a frontage of 75 feet on Broadway and the avenue. This enormous area has now been transformed to suit the requirements of the electric cab service, and, as will be seen, it is admirably situated for this purpose on account of its large and unobstructed interior.

The offices of the company are located on the main floor at the Broadway end, and space has been set aside at the office end for the drivers' room and repair shop. The remainder of the ground floor is divided into two main portions, one-half being occupied by the battery room, which measures 37 by 100 feet. At one end of this room is set the large electric crane for handling batteries, as explained more fully below. Above this space is a large room intended for the storage of unused vehicles, with

INTERIOR VIEW OF CHARGING STATION OF THE ELECTRIC VEHICLE CO., NEW YORK, SHOWING VEHICLE, HYDRAULIC RAMS, CRANE AND BATTERY TABLES.

will bear out the truth of the above statements by a close study of the apparatus and methods employed. But not alone in the design of vehicles, but, as will be seen by the description of the New York Electric Vehicle Station, given below, the entire service has been brought to a high state of perfection in this country.

It was eighteen months ago that Messrs. Morris & Salom, of Philadelphia, built twelve electric vehicles for service in the city of New York. These were in successful operation for over a year, when the demand for horseless vehicles far exceeded the supply, and led to the organization of a large corporation called the Electric Vehicle Company, whose intention it was to give to the metropolis as complete and satisfactory electric cab service as could be furnished. To carry this into effect 100 electric vehicles were ordered, very much after the pattern of the original twelve, with the necessary changes suggested by a year's severe service, running over all classes of pavement.

The next step was to erect a charging station having ample storage capacity for the carriages and fulfilling numerous conditions in order to give economical and in every way satisfactory service. Among these might be mentioned convenience of location for rendering service to the greatest number of patrons;

the exception of those which are on the floor below, charging or being cleaned.

In order to elevate the batteries to this room two large elevators have been installed. The carriage loading machinery, which will be referred to later, is located at the front end of the battery room. The cab, as it comes in from service, is backed up into this space, is automatically unloaded, and when not to be used immediately, is set aside for cleaning. If, however, it is to be immediately used again the discharged batteries are automatically taken out and a new set inserted, all within a space of about two minutes—less time than it takes to unharness a horse.

Before going into the detailed description of the equipment of this modern electric stable, on which a vast amount of skill and care has been bestowed in order to have perfect arrangement for the vehicles and batteries, a brief description of the cabs themselves as well as their equipment will prove of interest.

The electric cab, as stated above, was patterned after the type originally designed by Messrs. Morris & Salom, and resembles the ordinary hansom cabs, with the exception that it has a large compartment behind the carriage proper for holding the batteries. It has been the object of the designers to produce a vehicle embodying all features of the most modern carriages and to sacri-

INTERIOR OF BATTERY ROOM, IN CHARGING STATION OF THE ELECTRIC VEHICLE COMPANY, NEW YORK.

ELECTRIC HANSOM OF THE ELECTRIC VEHICLE COMPANY, NEW YORK, SHOWING HYDRAULIC RAM FOR SIDE ALIGNMENT AND BATTERY IN POSITION FOR LOADING.

fice if possible none of their graceful lines and lightness. The chief difference, of course, is that this electric cab has four wheels instead of two, and tires which bespeak luxurious comfort at first sight. The tires are no less than 5 inches in diameter and pumped to 60 pounds pressure. The vehicle, including the battery, weighs nearly 3,000 pounds, has a wheel base of 4 feet 7½ inches and a gauge of both front and rear wheels of 4 feet 10 inches. The front wheels support the carriage body and the two rear wheels are used for steering purposes.

The construction of these wheels is claimed to be superior to those of any other make, two ½" stamped steel plates serving in lieu of spokes. These hubs are fastened to the inside edges of the metal rim and diverge towards the hub, forming a hollow space within. The diameter of the space, including the tires, is

flexibility and prevent unnecessary jarring. The steering mechanism of the vehicle is of an improved design. As will be seen in the illustration, the steering lever, which is situated in front of the driver's seat, is 26 inches in length and is moved forward and backward by the operator. The independence of each set of wheels is a notable feature in these vehicles, and the great flexibility of every portion of the mechanism is noteworthy.

STORAGE BATTERY EQUIPMENT.

Each vehicle is equipped with 48 storage cells of the Electric Storage Battery Company's manufacture. It has a rated output of 100 ampere hours at the normal discharge rate. Each cell is encased in a rubber jar and consists of two Manchester positive and three chloride negative plates and weighs 26 pounds, making

OPERATOR IN POSITION FOR REMOVING A SET OF BATTERIES FROM A VEHICLE.

BATTERY CHARGING PANEL.

36 inches, all wheels run in roller bearings and have double ball thrusts. Each set of wheels is driven by a motor, and there is no gearing connecting them.

MOTORS.

The motors used in these carriages were built by the Westinghouse Electric and Manufacturing Company and are of a special waterproof ironclad construction, being very similar to ordinary street car motors. With a pressure of 80 volts at the battery terminals each motor develops 2 h. p., or 4 h. p. combined. The motors are geared to the driving mechanism in a manner similar to that employed for railroad motors, as is clearly shown in the illustration of the suspension mechanism of the carriage. The gears are so fitted to the wheel that the transmission of the strains is almost directly to the rim instead of passing through the web or spokes. Several rubber cushions and springs placed between the motor and the frame give the arrangement great

the total weight of the battery carried by each vehicle 1,248 pounds. The cells are placed on wooden trays, which fit into the battery compartment in back of the vehicle, into which they can be inserted as a unit, a matter of much importance and convenience.

The connections between the cells are burnt so as to insure good and permanent contact. When shoved into place the battery makes connection automatically with the motor and controller by means of contact springs, which are clearly seen in the engraving showing the back of the vehicle open for inspection with the battery in position. This portion of the carriage is suitably lined so as to prevent any spilled acid from attacking the woodwork, and is provided with channels to drain off the acid.

STEERING MECHANISM.

Besides the steering lever described above, the operator has

within easy reach the controller switch, which imparts a rotary motion to the controller cylinder, as well as a reversing switch. This is provided with an interlocking arrangement, which prevents the carriage from being reversed until the speed controller has been brought to a zero condition. The reversing switch is operated by the driver's foot, and ordinarily is in the position to go ahead. The controller allows three speeds to be obtained,

STEERING MECHANISM OF ELECTRIC VEHICLE.

namely, six, nine and fifteen miles per hour. The diagrams shown herewith illustrate the connection between motor, batteries and controller. The series parallel control is used, and with one charge of battery twenty-five to thirty-five miles of road can be traversed.

Besides the above switches there is an emergency switch for the purpose of shutting off instantly all current from the motor. This is under control by a kick of the operator's foot; a kick

MOTOR SUSPENSION AND BRAKE MECHANISM.

removes a key handle and opens the circuit. When this key has been removed no outsider can turn on the current and cause a runaway. The brakes are applied by means of a foot lever and are of the double acting shoe type, as shown.

It may appear from the number of switches to be operated that the motorman will have his hands full, but it has been demonstrated that the design and location of the controlling mechanism enable the operator to have perfect control of the vehicle and steer it easily and rapidly past any obstacle or through narrow passages.

It may be of interest to note that every part of the vehicle as well as the entire station equipment has been duplicated, so that in case of a breakdown the service will not be interrupted. Another important feature is that the battery may be charged with-

BOOSTER DYNAMO IN ELECTRIC VEHICLE CO.'S STATION.

out removing it from the vehicle. This is accomplished by means of receptacles and plugs in the battery box and on the charging table.

The hansoms above described are intended to carry two passengers, the operator and light baggage. The company, however, have delivery wagons and other styles of carriages in oper-

MOTOR CONTROLLER UNDER OPERATOR'S SEAT.

ation in the city and are now having built broughams and electric 'busses for heavy passenger service.

METHOD OF CHARGING THE STORAGE BATTERIES.

The charging of the batteries is done from the local Edison three-wire system, 350,000 c. m. conductors entering the building at the Broadway side. Three pole switches on the north wall connect them to 1,500,000 c. m. cables, which are led to the main switchboard. The switchboard, shown in the engraving, consists of nine white marble panels each 3 ft. 1½ in. in width, making

BATTERIES IN POSITION IN BACK OF VEHICLE.

the total length of the switchboard 28 ft. 1½ in. From the switchboard a number of busses are run to the charging panels, each bus being of a different potential, for reasons explained later. Four of the panels of this board control the positive side of the charging busses and four are connected to the negative side of the circuit. Switches connect these charging busses to the battery racks, each positive and negative bus being connected to its respective panel by means of a single pole switch, an under and overload I. T. E. circuit breaker and a large rheostat for regulat-

ing the potential. The first and fifth busses, however, by means of a double-pole double-throw switch, can be connected with a booster dynamo of $7\frac{1}{2}$ h. p. capacity at 220 volts pressure, built by the Western Electric Company. One of these boosters is used on the positive and one on the negative bus. These ma-

CONNECTING SPRINGS IN BATTERY COMPARTMENT OF VEHICLE.

chines have a capacity of 200 amperes at from 5 to 75 volts, and are placed on a wooden platform above the switchboard. The remaining panel at the right is used for light and power instruments and switches. Before following through the operation of charging a set of batteries, it should be stated that the company have facilities for charging 150 sets of batteries of 48 cells each, or 50 per cent. more than is required when all vehicles are in service. The batteries when not in use are placed on the separate trays referred to above and stored away in the battery racks, of which there are eight rows on the main floor, which is covered with cement. Thus each tray of cells has its own compartment built of heavy and well-seasoned yellow pine timber, coated with water

CHARGING TABLE AND GRAPPLING DEVICES.

and acid-proof paint. No metal was used in the construction of these racks. They are so arranged that access can easily be had to any part without removing it from its compartment. When a battery is being placed on a charging table by means of the crane it is automatically connected with it and the charging circuit by an ingeniously constructed lever. The two sections of each set of cells are connected together in series, and the two remaining terminals are connected to the Edison terminals by means of switches referred to above. The purpose of the four charging boosters is as follows: When a battery returns to the station it is connected to the lowest of the busses. This is done by a four-

point switch on the switchboard which connects the battery to any of the busses through a form of solenoid ammeter. These meters are provided with telltale indicators in the form of colored lamps set at the charging current, which is 20 amperes low and 50 amperes high.

We are now ready to follow a set of batteries through a charging operation. It is first placed on the charging table and connected to the lower pressure, which will allow the proper charging current to pass into the battery. At this charge its voltage rises and the current decreases. When it drops to the point at which the indicator is set the lamp is lighted and the switchboard operator knows that it is time to switch the battery on the higher

EXTERIOR VIEW OF CHARGING STATION, ELECTRIC VEHICLE CO., NEW YORK.

bus. The current is then increased by the higher voltage, and the signal lamp is cut out until the current drops again, and so the operation proceeds. If it is desired to charge the battery quickly it is only necessary to connect it at once to one of the higher busses, but this will have the effect of having the current fall to zero when the battery is fully charged.

Naturally, the charging of the batteries creates fumes, and these are withdrawn by a 40-inch exhaust fan, which is placed on the upper floor and is driven by an electric motor.

It may be further stated that the batteries can be charged from connecting plugs located at the forward end of the battery

VIEW OF ELECTRIC VEHICLE COMPANY'S CAB.

room without removing them from the battery box of the vehicle.

APPARATUS FOR HANDLING THE BATTERIES.

In the design and construction of the manipulating devices for the vehicles and batteries the greatest ingenuity and foresight

has been displayed, and the system as it stands to-day leaves nothing to be desired in simplicity and rapidity of operation.

It has been the aim to reduce the labor and expense connected with the handling of the vehicles and batteries to a minimum

inghouse four-pole motors, each of 5 h. p. capacity, receiving current from trolley wires suspended from the crane bridge. On each side of the operating cab are suspended four electric battery hoists, each having a capacity of one ton. These hoists are sus-

MAIN SWITCHBOARD IN STATION OF ELECTRIC VEHICLE COMPANY, NEW YORK.

by employing automatic devices throughout, which can be handled by unskilled labor. The manner in which this has been accomplished is simply marvellous, one man being able to unload and load a carriage with batteries by means of a set of levers

pendent directly over the battery racks and carry a grappling device consisting of two heavy iron jaws, as shown in the engraving. These jaws are operated by a set of chains, one for hoisting and the other for imparting motion to the grappling arms.

SIDE VIEW OF ELECTRIC VEHICLE, SHOWING DETAILS OF CONSTRUCTION.

from his position in the operating cab, suspended from the centre of the electric crane. This crane, which runs the entire length of the battery room, has a capacity of eight tons, and was built by William Sellers & Co., Philadelphia. It is operated by West-

Each hoisting drum is operated by a worm-gear electric motor.

When a vehicle comes into the station and has been placed in position by specially designed hydraulic machinery, described

further on, the grappling device runs out and withdraws the empty battery to the conveyor, which consists of heavy iron bars with upward projections, into which the battery tray fits. This loading transfer table, which is electrically operated and is in reality a link-conveying machine, extends across the entire front of the battery room. The conveyor consists of eight sections, and as soon as the empty tray has been deposited it is moved one section until it is opposite the vehicle, when a charged battery is pushed into place by the grappling device, explained above. The contacts in the vehicle are made by springs already referred to, which rub against the sides of the tray.

The empty battery is now carried by one of the lifting clutches and placed upon the charging table, and a charged one is de-

entire vehicle can therefore be shifted in any direction until it is in perfect alignment with the conveyor table. As the weight of the battery in the vehicle depresses the platform several inches, another alignment is necessary after the cells have been removed. This removal is accomplished by means of an hydraulic ram centrally situated in back of the conveyor table, which can be clearly seen in several of the illustrations. This hydraulic pulling and pushing ram, as it might be appropriately called, has its cylinder on a level with the conveyor table, across which the long plunger projects. When used for unloading a vehicle this plunger comes forward and engages a pair of hooks with sockets in the end of the tray, pulling the latter out of its compartment on the return stroke. When loading a vehicle the plunger simply

REAR VIEW OF ELECTRIC VEHICLE, SHOWING DETAILS OF CONSTRUCTION.

DIAGRAM OF CONTROLLER CONNECTIONS FOR THREE SPEEDS.

posited on the conveyor for the next vehicle, which comes in to be supplied with a charged set of cells. This all seems like a very simple operation, and so it is, for, as stated above, one operator can perform it in the short period of two minutes. But it must be remembered that a great deal of time and money was expended in designing special machinery for procuring these facilities, principal among which should be mentioned the hydraulic rams which place the vehicle in the exact position for unloading and loading.

In front of the conveyor table are two car-loading platforms on a level with the cement floor of the building. These platforms are mounted on wheels and can be moved in line with the conveyor table. The platform is divided into two parts, each having four wheels and being perfectly aligned and centered by means of weights. In this way each pair of wheels of a vehicle situated on the platform has an independent car to itself and the

pushes the tray into position. The hooks are released from the sockets on the trap by means of a lever, which can be operated by the man in the crane cab.

The hydraulic ram for lifting the vehicle consists of two vertical cylinders built on a solid brick foundation beneath the platforms on which the vehicle is run. The plungers of these cylinders are attached to raising bars, and when actuated project through openings in the platform, one plunger raising the body of the vehicle and the other the battery compartment. After this operation the other hydraulic rams located on each side of the platform come into action for the side alignment of the vehicle. The bars of these machines connected to plungers of horizontally placed cylinders act closely to the hub centres of the wheels and extend so far as to strike the steering and driving hubs at about the same time. These bars, used for centring the vehicle, have different movements, the one opposite the front wheel having a

travel of 11 inches and the other one 7 inches. The rams are returned to their normal position by heavy weights, and the amount of their travel is predetermined for placing the vehicle into the required position, both in regard to height as well as getting it centrally located in front of the conveyor table. All the hydraulic machinery is operated by means of an electrically driven Gould triplex pump. This pump feeds at a pressure of 150 pounds to the square inch, a pressure tank 3 feet in diameter and 5 feet deep sunk into the floor between the loading platforms. Pipes extend from this to the several controlling valves of the machinery described above.

The two vehicle elevators, which are operated by C. & C. electric motors, have a capacity of $2\frac{1}{2}$ tons and operate at a speed of 100 feet per minute. Between these elevators an emergency loading station is located, supplied with machinery for loading and unloading the vehicles similar to that in the main room, with the exception of the side centering device.

CONCENTRATION OF CONTROL, INSPECTION OF VEHICLES AND COST OF SERVICE.

As will be seen from the above description, perfect concentration of control has been established by locating all operating levers within easy reach the operator in the crane cab and enabling him to see the signal lights on the switchboard and operate the switches thereon. Nevertheless, every piece of moving machinery is provided with interlocking and safety devices, so as to prevent any accident in case the operator should neglect his duty. Besides, as already stated, the automatic features of the entire equipment enable one man to operate it with rapidity and thus insure economy and efficiency of service. Each vehicle before it leaves the station and after it returns is carefully inspected by competent men and thoroughly cleaned, and the battery equipments, as well as the vehicles and other apparatus, are con-

after one has gained an idea of the enormous amount of time and money which has been expended by the promoters. First among those to whom credit should be given is the chief engineer, Mr. G. Herbert Condict, whose general design was followed in the construction of the station and the various details, assisted by Mr. A. W. Gilbert, the constructing engineer. The officers of this enterprising company are: Mr. Isaac L. Rice, acting president; Mr. Frederic Vieweg, general manager, and Mr. G. Herbert Condict, chief engineer.

SOCIETY & CLUB NOTES

Boston Meeting of the American Street Railway Association.

The meeting of the Association will last from September 6 to 10 inclusive, headquarters being at the Brunswick, and sessions being held at the Charitable Mechanics' Building, where the exhibits will be. There are to be several entertainments and excursions, including a clambake at Nantasket Beach, trips to Plymouth, Concord and Lexington, and a trolley ride to Norumbega Park. The papers to be read are as follows: Tuesday—"Comparative Earnings and Economy of Operation between Single and Double Truck Cars for City Use," Richard McCulloch, Electrical Engineer, Cass Avenue and Citizens' Street Railway Companies, St. Louis, Mo.; "Municipal Owner-

HYDRAULIC RAM FOR SIDE ALIGNMENT.—PLAN VIEW.

stantly kept in repair and improved upon. Tests of efficiency are frequently made, and an extensive series of them are now in course of preparation, the results of which will undoubtedly prove of interest and value.

The public of the metropolis, recognizing and appreciating the high efficiency of the service, are freely patronizing the electric cabs. Besides transporting the passenger with far greater dispatch, the fare charged is only about one-half that charged for vehicles drawn by horses. For each passenger the fare is 30 cents for the first mile and 15 cents for each succeeding one, or the cab may be hired per hour for a reasonable sum. The cabs are located at the most prominent corners and thoroughfares, or may be summoned by telephone or messenger from the station. As a larger number and greater variety of vehicles are built and the streets of the city improved, the service will grow in public favor and patronage. This is surely to be hoped and expected

The Fiftieth Anniversary Meeting of the American Association for the Advancement of Science.

(From Our Special Correspondent.)

THE fiftieth anniversary meeting of the American Association for the Advancement of Science began at Boston on Monday, August 22, with a session of the Council of the Association. At 10 a. m. the general meeting was held in Huntington Hall of the Massachusetts Institute of Technology. From the number of delegates present and the character of the papers presented this meeting was without doubt the most important ever held by the association. Delegates representing all branches of scientific activity were present from the great educational centres of this country, besides many who came from Canada and Europe to represent their various countries.

The arrangements, which were in charge of the local committee, were superb, and nothing was spared to give the members of the Association the best the city could afford in every detail. The various clubs about the city gave the delegates special attention for their entertainment, together with the excursions made to the beautiful suburbs of the city. Boston fairly outdid itself.

The first general session of the Association was held on Monday at 10 a. m. in Huntington Hall. The large auditorium was crowded to listen to the various addresses. The meeting was called to order by the retiring president, Wolcott Gibbs, of Newport, R. I. After prayer by the Rt. Rev. William Lawrence, Bishop of Massachusetts, addresses of welcome were delivered by His Excellency, Roger Wolcott, Governor of Massachusetts; Josiah Quincy, Mayor of Boston, and President Craft, of the Massachusetts Institute of Technology.

Governor Wolcott was in fine voice, and throughout the whole of his forcible address was listened to with marked attention by his large audience. He extended a most cordial greeting to the Association and welcomed all its members back to the Association's place of birth. He also spoke of the great work being done by scientists in their search for truth and urged upon the Association the continuance of its noble pursuit.

Mayor Quincy said that Boston was the host of the Association at this, its semi-centennial, and was grateful for the privilege of entertaining it, fully appreciating the favor conferred by holding its anniversary in Boston. He also dwelt upon the practical application of the principles of science to municipal government.

President Crafts, on behalf of the Massachusetts Institute of Technology, welcomed the delegates and spoke of the advantages of scientific research.

The chairman of the local committee announced that the social part of the programme had been much enlarged, and included excursions to various points of interest about the city. He said that it was the intention of the committee to make Wednesday and Friday gala days, and that arrangements had been perfected for the continuous entertainment of the members of the Association.

A message was read from the Russian Geological Committee of St. Petersburg, sending to the American Association the good wishes and congratulations of that society.

After the reports of several committees were passed upon the first general session was closed.

The various sections then took up the reading and discussion of papers.

No general session was held by the Association on Monday afternoon, but the nine different sections met and papers were presented by the vice-president of each section, which bore directly upon the work of the respective sections. One of the most interesting papers was that by Professor Smith on "The Electric Current in Organic Chemistry." In this paper Professor Smith outlined the growth of this branch of electricity, and said that it had been a stepping-stone to great advances in other branches of electrical science. The use of the current in electrolytic solutions had in many cases led to a complete reversal of many previous ideas as to the composition of important solutions and had been of immense advantage to the industrial side of the question.

TUESDAY, AUGUST 23.

Tuesday was a day of serious work for the members of the Association. Each of the sessions held two meetings devoted to

the presentation of special scientific subjects. It was found that all of the papers could not be brought forward, and as a result a large proportion were not read before the Association.

The most important announcement of the day was that of Mr. Charles F. Brush, who gave in detail the process of discovery of a new gas in the atmosphere, which he at present terms etherion.¹

The afternoon excursion about Boston Harbor was the most largely attended excursion of the day. In the evening from 9 until 11 the Public Library was open to the members. Mayor Quincy gave a dinner at the Union Club to the officers and guests of the Association. Among the foreign guests were Prof. Chaney, delegate of the French Government; Prof. Cooke and Prof. Howard, of London; Prof. Galbraith, of Toronto, and M. Paul du Chaillu, the African explorer.

WEDNESDAY, AUGUST 24.

Wednesday was Salem day. Several excursions were made to this historic point, and, as a consequence, very little work was done at the headquarters of the association. The first party started at 7:45 in the morning. This party was composed of engineers and sanitarians, and went to the Metropolitan Water Works at Clinton. A party of eighty went to Lawrence, where several big print works were visited.

The chief event of the day, the Salem excursion, left early for this place. The sail down the bay afforded a fine view of the harbor and islands.

A landing was made at Salem Willows, where the visitors became the guests of the Essex Institute of Salem. Here the local committee served the scientists with an old-fashioned New England shore dinner. The party then divided into groups and, under the guidance of the local committee, were shown the points of historic interest about the place.

THURSDAY, AUGUST 25.

The members began to gather as early as nine o'clock, and spent a busy day at the Massachusetts Institute of Technology.

Besides the regular sectional meetings, the day's programme included several features deserving of special note. Paul du Chaillu, the African explorer, delivered an address on "The Norsemen, the Conquerors of Britain," in which he dwelt on the importance of this race in the history of civilization, criticising the historians for the unimportant place they give this people in the annals of history.

By Thursday evening several of the sections had finished their labors and disbanded for the current meeting.

The Council of the Association elected Prof. Edward Orton president for the coming year, and decided upon Columbus, O., as the place for the next annual convention of the Association. Prof. Edward Orton is State Geologist of Ohio; he was graduated from Harvard University and has held many important positions in scientific work. He has had charge of the work of the State Survey since 1881.

FRIDAY, AUGUST 26.

Friday was known as Cambridge Day. The members of the Association were by special invitation of the President and Fellows guests of Harvard University for that day.

All departments of the University were open throughout the day for inspection by the members of the Association, and in many departments special exhibitions were given for the benefit of the members. In the evening President Elliot delivered a timely and scholarly address to the guests in Saunder's Theatre. His subject was, "The War's Lessons." He defined his position as not opposed to the army and navy, but in favor of larger expenditure for the constructive arts. He said that the modern soldier was a scientist, and he must know how to use weapons of precision and scientific instruments intelligently. "This war," he continued, "brought out in a very forcible manner the fact that the wider the education of the people, the more free industries open to the people, the greater is the military power."

SATURDAY, AUGUST 27.

The last general meeting of the convention was held this morning at 10:30 o'clock. Many famous scientists were upon the platform. Many reports were read, the most interesting being that of the permanent secretary. This showed that 903 delegates had registered during the convention, 158 being from New York. Canada, England, France, Germany, Brazil, Japan and Australia

¹See page 203.

were each represented by one or more delegates. Four hundred and forty-three papers had been read, and almost \$6,000 surplus was in the treasury of the Association.

Classified Digest of U. S. Electrical Patents Issued August 16, 1898.

Batteries, Primary:—

PRIMARY BATTERY. Walter Rowbotham, London, England, 600,298. Filed Feb. 24, 1898. A new construction and arrangement of battery whereby local action is quite avoided when the battery is at rest, and in details intended to permit of the battery being continuously charged and discharged of its working fluids while using iron instead of zinc for the active plates.

COMBINED BATTERY AND ELECTRIC CELL. Jules Celestin, Dageoneau, Beaufort, France, 600,142. Filed Jan. 15, 1896. A cell containing sulfate of copper, an interior cell contained therein and comprising a rectangular framework and membranes secured upon this framework and constituting the walls of the interior cell, a zinc element and dilute sulfuric acid contained in the interior cell, suspension bars adapted to suspend the articles to be plated, circuit connections between the zinc plate and the bars and one or more perforated lead plates in the interior cell upon which a copper deposit will be made.

Conductors, Conduits and Insulators:—

METHOD OF AND APPARATUS FOR MAKING ELECTRICAL INSULATION CONDUITS. Hugo Gallinowsky, St. Louis, Mo., assignor to the Lithosite Mfg. Co., same place, 600,004. Filed Nov. 15, 1897. Consists in submerging fibrous material in a bath of oxy-chlorid cement, saturating the material from both sides, winding it on a mandrel before the cement completely sets, by suspending it by one end so that the mandrel will slip out.

MEANS FOR FASTENING INSULATOR PINS TO CROSS-ARMS. Loron Mitchell, Augusta, Ga., 600,288. Filed May 10, 1898. An insulator pin having its shank provided with a groove triangular in cross-section, and a locking device carried by this groove and adapted for frictional engagement with the wall of an opening into which the shank of the pin may be passed.

ELECTRICAL CONDUIT BOX. Hubert Krantz, New York, 600,356. Filed May 6, 1898. A split conduit box provided with corresponding semicircular rims on the two parts of the box to form the outlet openings for the conduits, in combination with closing discs held in place by the two parts of the box when fitted together.

Controlling Devices:—

ELECTRIC CONTROLLER. Joseph D. Forrer, Johnstown, Pa., assignor to the Steel Motor Co., Ohio, 600,092. Filed July 11, 1898. A pair of concentric shafts, operating levers for each shaft, means for preventing the removal of one of the levers except when it is at a predetermined position, and independent means for preventing the lever from being removed except when the other shaft is at a predetermined position.

ELECTRIC CIRCUIT CONTROLLER. Nikola Tesla, New York, 600,245. Filed Dec. 2, 1897. The combination with a receptacle of a conductor or series of spaced conductors, a nozzle or tube for directing a jet or stream of fluid against the same, the nozzle and conductor being capable of movement relatively to each other, and means for maintaining a circulation of conducting fluid, contained in the receptacle, through the nozzle, and dependent for operation upon such relative movement. (Described in the issue of Aug. 25.)

ELECTRIC CIRCUIT CONTROLLER. Nikola Tesla, New York, 600,246. Filed Feb. 23, 1898. Similar to above.

ELECTRIC CIRCUIT CONTROLLER. Nikola Tesla, New York, 600,247. Filed March 12, 1898. Similar to above.

ELECTRIC CIRCUIT CONTROLLER. Nikola Tesla, New York, 600,248. Filed March 12, 1898. Similar to above.

ELECTRIC CIRCUIT CONTROLLER. Nikola Tesla, New York, 600,249. Filed March 12, 1898. Similar to above.

ELECTRIC CIRCUIT CONTROLLER. Nikola Tesla, New York, 600,251. Filed June 3, 1897. Renewed June 15, 1898. Similar to 600,245.

SYSTEM OF CONTROL OF ELECTRIC MOTORS. Edwin R. Gill, Englewood, N. J., assignor to the Invention Developing Co., New Jersey, 600,274. Filed April 4, 1898. A system whereby the power regulation is primarily dependent upon movement of the motor itself, thus insuring any desired degree of generation of counter electromotive force before a predetermined resistance has been cut out.

Dynamos and Motors:—

ELECTRIC MOTOR. Rudolf Eickemeyer, Yonkers, N. Y., 600,015. Filed Jan. 5, 1891. A reversible electric motor coupled to the hoisting mechanism, provided with a system of field coils, and one or more governing coils, and means for supplying the governing coils, with independent electric currents opposite in direction to those carried by the field coils, and means for furnishing to the governing coils, currents which are effective only when the motor and elevator are moving too rapidly.

Miscellaneous:—

ELECTRIC ELEVATOR. Rudolf Eickemeyer, Yonkers, N. Y., 600,016. Filed May 3, 1892. The combination with the traveling car body or platform of a compound motor, a resistance in shunt relation to the series coil of said motor, and a solenoid automatically controlling the magnetizing power of said series field coil by gradually short-circuiting said resistance.

MEANS FOR INDICATING A SHIP'S ROLL. James J. Hicks and Giles H. Zeal, London, England; said Zeal assignor to said Hicks, 600,231. Filed Nov. 18, 1897. An annular tubular glass chamber half filled with mercury, and means for carrying such chamber and oscillating it in a vertical plane.

ELECTRICAL IGNITER FOR GAS ENGINES. Nikola Tesla, New York, N. Y., 600,250. Filed Feb. 17, 1897. Renewed June 15, 1898.

Depends for its operation upon the production of a sudden electric discharge at a given instant or at predetermined intervals of time.

WINDING MACHINE. Emmett J. Satterwhite, Falls City, Neb., assignor of two-thirds to Fred. E. Farington, Charles W. Farington and Theodor F. Sullivan, of Richardson County, Neb., 600,300. Filed Sept. 10, 1897. A new and improved winding machine arranged to accurately wind the desired amount of wire on a core of the desired length.

SHIP'S COMPASS. Robert Oliver, New York, N. Y., 600,363. Filed Sept. 11, 1897. A compass card having straight, permanent bar magnets arranged thereon, parallel to a north and south meridian and permanent U-shaped, or horseshoe, magnets arranged with their legs on opposite sides of the equatorial line.

Railways and Appliances:—

MOTOR CAR. Charles Otis Palmer, Cleveland, O., 600,043. Filed April 18, 1894. Renewed Jan. 25, 1896. Means for automatically maintaining a uniform tension of the driving rope notwithstanding the driven pulley is being moved at the same time the power is being transmitted.

ELECTRIC BRAKE. Ernest B. Skinner, Ogden, Utah, 600,124. Filed Oct. 30, 1897. Consists of a solenoid and its plunger for operating the brake mechanism; a second solenoid disposed at right angles to the first and a lever connected at one end of the plunger of the smaller solenoid and at the other end to links carrying a shoe, used for braking.

ELECTRICAL TRACTION. William Kingsland, Llandudno, England, 600,188. Filed Dec. 23, 1897. A continuous main electrical conductor, and sectional working conductors from which the motor car directly collects the current, and a number of sectional auxiliary conductors, one such for every sectional working conductor, and through which auxiliary sectional conductor the current is passed from the main conductor to the sectional working conductor.

ELECTRIC RAIL BOND. Joseph S. Tucker, Chicago, Ill., 600,252. Filed Jan. 20, 1897. A rail bond comprising a conductor having its ends provided with enlarged tapered heads provided at their smaller ends with flanges, in combination with bushings adapted to encircle these heads.

SWITCH AND SWITCH OPERATING MECHANISM. James P. Orr and George H. Fugh, Pittsburg, Pa., 600,202. Filed Nov. 9, 1897. A railway switch, comprising a tongue, a track section, electrical means for moving the tongue and track section vertically, one section being moved downward as the other is moved upward and means carried by a car for opening and closing the electrical circuit.

Telegraphs:—

ELECTRIC TELEGRAPHY. Oliver Joseph Lodge, Liverpool, England, 600,154. Filed Feb. 1, 1898. (Similar to the system described in The Electrical Engineer, Feb. 24, 1898.)

FIRE ALARM. Hilmar Tersling, Copenhagen, Denmark, assignor to Johannes Caroe, Niels Schmidt and Emil Schiemann, of same place, 600,309. Filed March 15, 1897. A fire alarm constructed to reduce to a minimum the danger of sounding false alarms, and it is characterized by a mechanical alarm sounding in the immediate vicinity, and by a mechanism moving in unison with the mechanical alarm, whereby an electrical circuit is influenced to sound a distant alarm.

Telephones:—

TELEPHONE SYSTEM. Alfred F. Swan, Bayonne, N. J., 600,173. Filed Sept. 20, 1897. A movable switch arm operated from the switch barrel and adapted to cut the talking set in and out.

TELEPHONE SYSTEM. Charles E. Egan, Burton L. Lawton and Ernest C. Wilcox, Meriden, Conn., 600,229. Filed April 9, 1897. Spring jacks, each provided with a central telephone connecting spring, a generator connecting spring and a subscriber's communicating spring; a plunger fitted to reciprocate in each spring jack to engage either of the first two named springs, and a pair of connected plugs, each fitted to operate a plunger and provided with a metallic nib fitted to engage a subscriber's communicating spring.

TELEPHONIC MEASURED-SERVICE SYSTEM. William W. Dean, Boston, Mass., assignor to the American Bell Telephone Co., of same place, 600,331. Filed Nov. 16, 1897. Consists in combining a two-party main telephone circuit with two call-registering or call-counting mechanisms placed at the central station, and each operated to produce a record only when their electromagnets are excited by two successive current impulses.

TELEPHONE REPEATER OR RELAY. John Stone Stone, Boston, Mass., assignor to the American Bell Telephone Co., of same place, 600,374. Filed Dec. 20, 1897. An improved telephone relay adapted to be placed at the junction of two telephone circuits extending from different terminal stations for the purpose of automatically repeating the conversation transmitted over one circuit into the other.

The Condict Controller Patent.—The Nassau Electric Co. Enjoined.

Judge Lacombe, of the United States Circuit Court for the Southern District of New York, last week issued preliminary injunctions on the Condict patent controlled by the General Electric Company, against the Nassau Electric Railroad, of Brooklyn, enjoining the further use of the electric car controllers, which were made by the Steel Motor Company, and against the Walker Company, enjoining its manufacture of the several types of series parallel car controllers made by it.

The operation of this injunction is suspended until the next session of the Court of Appeals to give the defendants an opportunity for appeal. This is the same patent recently sustained at final hearing by Judge Townsend.

Death by Accident of Dr. John Hopkinson.

As we go to press a cable dispatch announces the death of Dr. John Hopkinson, the celebrated English electrical engineer, and his son and two daughters, who were killed while ascending the Dents de Veisivi, in the Canton of Valais, the mountains of which are among the highest in Europe, and which are exposed to furious torrents and destructive avalanches. The party had gone on their perilous trip without the assistance of a guide. Dr. Hopkinson had intended starting for New York on September 28, the trip to be made in connection with a syndicate which he was forming for the purpose of developing some of his inventions.

Frank H. Stewart & Co.

A very complete and interesting catalogue of electric bells, electric gas lighting, telegraph and speaking tube supplies has just been issued by F. H. Stewart & Co., 35 North Seventh street, Philadelphia, Pa. It measures 9x12 inches, is handsomely bound and contains a complete index of a large number of electrical goods, such as batteries, annunciators, bells, push-buttons, gas lighters, telephone and telegraph supplies, motors, wire, insulators and battery gauges. The catalogue will be sent to any one on application.

A Quarter of a Million Horse Power.

This is the title of a very handsome and instructive booklet issued by the Westinghouse Electric & Manufacturing Company, Pittsburg, Pa. It contains a mine of information on electrical transmission by polyphase currents. It is indisputable evidence of the company's ability to transmit electrical power to any extent over any desired distance. Only a few of the best known plants installed by this company are enumerated, although the list comprises 185 plants in twenty-nine States and eight foreign countries. The distance over which the current is transmitted ranges from one to seventy-eight miles. Among the plants described and illustrated are the Niagara Falls Power Plant, the Helena Water and Electric Power Company's plant, the Niagara plant of the Canadian Niagara Power Company, the Dolgeville (N. Y.) plant and the Apple River Power Company's plant at New Richmond, Wis. There are also shown beautiful illustrations of the motors installed in Buffalo and intermediate points between there and Niagara and the installation in the Cumberland Paper Mills in Maine, nearly all of which have been illustrated in our columns. The remaining stations are simply enumerated, the size of generators, motors and transformers, the transmission voltage and the nature of the service being given. The book is beautifully printed, has a handsome cover and does great credit to the company. It will be sent to any one on application.

The Development of the Telephone.

This is the name of a very ingenious and instructive pamphlet sent to his customers and interested parties by Mr. E. C. Bickel, the general manager of the Elkhart Telephone Company, Elkhart, Ind., an independent exchange. The story is told of how the company was started, how the switchboard grew year by year, what the people have gained by the service, and what prospects there are for the future. The pictures on the left-hand pages tell a story by themselves. The first is a single panel board having a capacity of 100 subscribers, which was installed on December 1, 1895. The second picture shows a switchboard with 200 subscribers capacity, installed January, 1896. In June, 1896, an additional panel was added, making the capacity, 300 subscribers. The fourth picture shows a board with 350 subscribers, as it appeared in January, 1897, and the last picture shows the switchboard as it is to-day, with 500 subscribers capacity and

four operators, against one which appeared in the first picture. It is a pretty story without words and one which speaks volumes. Mr. Bickel also announces that as the initial expense of this little publication was rather out of proportion to local benefits, he is prepared to sell additional copies to other exchanges who are in their formative period for ten cents a copy.

An Advance All Along the Line.

Last week's stock market reflected admirably the sentiment of the business community, which is again reassured of the stable conditions of trade consequent upon the approaching signing of the treaty of peace. The number of shares dealt in on the stock exchanges shows vast weekly increases, indicating the eagerness of investors, while the prices obtained are tending steadily upwards.

Western Union sold around 95, with 18,315 shares dealt in. General Electric touched 41½, with 6,524 shares sold. New York Edison Illuminating sold at 133¾.

There was little change in the metal market. We quote the following market prices: Iron, Northern, No. 1 foundry, \$11.25; Southern, No. 2 soft, \$10.25; steel rails, \$18.50; lake copper, ingot, \$12.20; tin, \$16.15; lead, \$4.12½; spelter, \$4.80.

The Montauk Multiphase Cable Before the Association of Fire and Police Telegraph Superintendents.

AT the third annual convention of the National Association of Fire and Police Telegraph Superintendents and Municipal Electricians, held at Elmira, N. Y., last month, the Committee on Exhibits made the following report on the Montauk multiphase cable:

"The undersigned, a committee appointed to report on the exhibit of the auxiliary fire alarm and the new cable of the Montauk Multiphase Cable Co., as adapted to the system of the Gamewell Fire Alarm Telegraph Co., beg leave to report as follows:

"We find properly located and connected up one fire alarm box, arranged so as to be operated from an auxiliary sub-station also the proper arrangements and connections for automatically sending in an alarm of fire by means of multiphase cable, a fusible wire being burned through or cross connected by contact with a slight blaze or fire such as a match might cause. On the application of a very slight fire from a match, the multiphase cable was cross connected, thus throwing on an additional current of electricity, the composite wire was melted, thus opening properly another line, relieving a light current which has previously been in operation.

"By these simple means, the main box was pulled, the alarm struck on a local gong attached to the circuit, a warning bell rang to indicate that the line was in operation, and the instantaneous sounding of its alarm showed that all claims as to the merits of the purpose and operations of the apparatus had been fulfilled. It is simple in action, and reliable as a fire alarm adjunct.

"The Montauk multiphase cable is practically a substitute for a thermostat, and this cable being run in out-of-the-way places, or in dangerous localities in buildings where fire is liable to occur, really makes a continuous thermostat, ready at all times for action in case of fire or dangerous heat at any point where the cable runs."

The report was signed by the committee consisting of the following well-known gentlemen: Wm. Brophy, Inspector Wires, Boston, Mass.; M. W. Mead, Sup't Bureau of Electricity, Pittsburg, Pa.; Geo. F. MacDonald, Sup't Fire Alarm, Ottawa,

Canada; F. C. Mason, Sup't Police Telegraph, Brooklyn, N. Y.; W. N. Thompson, Sup't Fire Telegraph, Richmond, Va.

The gentlemen constituting this committee being all professional experts of national reputation, renders any action taken on their part of value and interest to the profession at large. The report denotes their approval of an important progressive step in fire alarm protection.

The Largest Arc Dynamo.

There is now nearing completion at the Rushmore Dynamo Works, Jersey City, what will be the largest arc machine ever constructed. It will operate on the new multi-circuit system lately perfected by Mr. S. W. Rushmore, and at 500 r. p. m. will supply two independent circuits of 150 ten ampere arc lamps each, or a total of 300 lights. This is claimed to be just double the size of the largest arc machine now in service.

The machine has four poles and resembles an ordinary constant potential generator. Unlike other so-called multi-circuit machines, the circuits are all in parallel and cannot be connected in series. Each circuit has a separate pair of brushes and regulation is effected by a simple solenoid acting on each brush rocker. There is no sparking, and either circuit may be open circuited or short circuited, with any load, without any effect upon the other circuit.

Mr. Rushmore is now designing a larger machine for direct connection to the Willans engine. These new machines will be put in under the fullest guarantee and it is expected that the efficiency will be nearly as high as in the latest type constant potential machines of the same kilowatt capacity.

Second Annual Outing of the Employees of the Conduit Wiring Co., Davis & Brussel, Successors.

The second annual outing of the employees of the Conduit Wiring Co., Davis & Brussel, Successors, was held August 21, 1898, at Donnelly's Grove, College Point, L. I. A most enjoyable day was spent in bowling, land and water races, etc. Amongst the visitors were Messrs. Olson and Harrington, of the Habirshaw Co.; Mr. Scribner, of the Bryant Co.; Mr. Kirkland, of the Circular Loom Co.; in addition to representatives of most of the large supply houses in New York. Mr. Davis, of the firm, was also present, and took an active interest in the games and other diversions. Messrs. Fenton, Koehler and Bennett were the committee in charge of the affair.

The Cleveland Electric Trading Company, Cleveland, Ohio.

THE business of this company, as indicated by the name, is chiefly trading in electrical supplies. This includes the buying of second-hand electrical machinery and appliances, overhauling, refitting and selling the same. They also deal in new stock, being selling agents for some of the first-class dynamo and supply manufacturers. They are also contractors for installing and equipping lighting and power stations, including the steam and engine equipments as well as the electrical features.

Mr. W. H. Pelton, the manager, is both an electrical and steam engineer, and has had a long experience in this line of work, both for others and on his own account. A stock of generators and motors, including both new and second-hand goods, is kept constantly on hand. Besides repairs to their own purchases, the shops are equipped for repairing armatures of all descriptions, and repair work is made an important part of the business.

It is a mistake to suppose that second-hand electrical machinery is necessarily worn and defective. It is put on the market usually because it has been superseded by heavier and later-date machinery in order to meet the exigencies of the larger demand for light and power. When redesigned, as is done in many cases by this company, it is about as good as new, and is offered at such a price as to make it an object to prospective purchasers. The contracting department of the business is prepared to undertake the installation and equipment of stations of any character, and guarantee all their work to be as good as the best. In short, the company is prepared to meet any demand along any of the

above lines that may be made and is ready to buy second-hand material to an unlimited amount.

The offices of the company are at 806 Cuyahoga Building.

JULIUS ANDRAE & SONS' COMPANY, of Milwaukee, have secured the agency for the famous Ericsson telephones in the Badger State. These telephones are all that is claimed for them and are proving themselves beyond a doubt the standard of the world. They are experiencing a healthy run on "O. K." batteries.

MR. JAMES HEALEY, who recently returned to Milwaukee from a trip through Northern Illinois in the interest of the Julius Andrae & Sons' Company, states that the business conditions in the rural districts are very favorable. The splendid crops of the season have made it possible for the farmers to put in telephones and necessities in the electrical line.

COOL. Almost entire Milwaukee is kept cool by breezes furnished by Lundell fan motors. Julius Andrae & Sons' Company, who are the Milwaukee selling agents, have succeeded in placing the Sprague goods in many of the largest local business houses, hotels and theatres, including the Alhambra Theatre, Palm Garden and Kroeger Bros.' large clothing establishment.

THE NATIONAL ELECTRIC COMPANY, located at 15 Michigan street, Cleveland, O., are reporting large electrical repair orders received during the last few months. They are at present rebuilding a number of large generators and are manufacturing small motors and experimental machines. A detailed description of the business of this company appeared in our issue of August 11, 1898.

WALKER COMPANY will exhibit at the Street Railway Convention, Boston, the following apparatus: Section of Walker underground conduit system, with car in operation, 15-L railway motor in operation, 15-L motor, open to show construction, No. 33 S. motor, mounted; No. 33 S. motor, open; set of 33 S. armatures, in various stages of construction; set of 33 S. motor parts; standard trolley, standard railway switchboard panels, with wattmeter, S. controllers in operation, solenoid partitions open and in operation.

MR. F. E. DRAKE, of the Walker Company, has been selected as electrical adviser to Commissioner General Ferdinand Peck of the United States to the Paris Exposition of 1900. Mr. Drake will sail for France with the Commissioner General and party on the steamer "La Touraine" from New York on September 3. He expects to return to this country about the middle of October, and will then resume his duties with the Walker Company.

MASON & RICHARDS CO., 314 Security Building, St. Louis, Mo., have issued a broadsheet notice to the trade relative to the agencies now in their hands, including Walker apparatus, Keystone Electric Co.'s machines, Keystone instruments, Partridge carbons, and a large number of other specialties.

BOONE, IA. The Boone County Telephone Co. has a capital stock of \$13,300 paid up. J. L. Stevens is president, and C. E. Deering secretary. The apparatus was supplied by the Western Telephone Construction Co., and a Sterling Electric Co. switchboard is now being added. There are 340 subscribers and 125 miles of toll line. The present board has a capacity of 400 drops. Rates are \$2.50 per month, business, and \$1 for residences.

ROCHESTER, N. Y. The Standard Electric Construction Company has been dissolved by E. H. Freeman and W. H. Tobey, but the business will be continued under the same name and style by E. H. Freeman and B. A. Vandy.

F. CROSELMIRE, Newark, N. J., the well-known manufacturer of platinum, has left for the Ural Mountains, Russia, to be away for several months. Mr. Croselmire goes to make contracts for and buy the crude platinum, which he refines at his extensive works in Newark.

A COMPLETE X-RAY OUTFIT, presented by the General Electric Company to the United States Government at the beginning of the war with Spain, is reported to have been the only apparatus which had worked satisfactorily on the hospital ship *Kelief*, in Cuban waters.

NEW YORK CITY. It is rumored and denied that the Metropolitan Street Railway Co. is to engage in electric lighting.

ADVERTISERS' HINTS

WILLIAM E. QUIMBY, 86 Liberty street, New York, advertises screw electric pumps, instead of screw steam pumps, as was erroneously stated in a recent issue.

JNO. R. ROEBLING'S SONS CO., Trenton, N. J., recommend the use of bi-metallic wire for overhead lines, stating that it possesses those qualities essential to good working, and the question of cost also appeals to the user.

THE AMERICAN ENGINE CO., 32 Raritan avenue, Bound Brook, N. J., call attention to the excellence of their direct-connected generating sets, and also to their belted generators and detached engines. Their latest production is a slow speed direct connected motor for driving large printing presses and other heavy machinery.

BIBBER-WHITE CO., 49 Federal street, Boston, Mass., say the name "American" was selected for their new "Welsbach gas-lighter" because "it has the good points of all others and no weaknesses." They also say that a trial order makes a regular customer.

THE NOWOTNY ELECTRIC CO., 212 Lawrence street, Cincinnati, O., publish an up-to-date list of the agents for their long-burning enclosed arc lamps possessing many advantages particularly their own.

PINS AND BRACKETS are advertised by the Electric Appliance Co., 242 Madison street, Chicago, Ill. All their pins and brackets are made either from the best split live oak or selected locust and are warranted sound and strong.

JULIUS ANDRAE & SONS CO., Milwaukee, Wis., say their telephones never disappoint. Their catalogue No. 10 is now ready for distribution.

THE GENERAL INCANDESCENT ARC LIGHT CO., 572 First avenue, New York, offer direct current enclosed arc lamps for several classes of service, and also alternating current lamps. They have some new circulars which may be obtained.

NEW ENGLAND NOTES

MONTVILLE, CONN. The estate of C. M. Robertson, recently lost by fire their boiler house. In order to obviate, if possible, a like experience in the future they have decided to put up a thoroughly fireproof construction in its place. The building will have steel framework, brick side walls and an absolutely fireproof roof, consisting of corrugated iron covering laid on the Berlin Iron Bridge Company's patent anti-condensation roof lining. Steel trusses will support the roof. The building is about 50 feet square, divided by a corrugated iron partition through the centre, making a boiler room and pump room. The ventilation is obtained by monitors on the ridge of the roof, having sash on the sides. The Berlin Iron Bridge Company are furnishing and erecting the steel work.

SOUTHERN NOTES

MR. HENRY WIDMER, 522 Custom House street, New Orleans, La., notifies the public that he is in the electrical construction field. He has the local sole agency for C. & C. dynamos and motors.

BRISTOL, TENN. The Bristol Virginia Corporation have just completed an artesian well and are now open to receive bids on pumping power, with plant sufficient to run some 75 arc

lights. Mr. C. W. Hannah will receive estimates on the power plant. Mr. H. J. Wilcox, Bristol, Tenn., would like to receive prices and estimates on lighting apparatus.

GEORGE A. CRAGIN, of Houston, Texas, representing Washburn & Moen Manufacturing Company, has brought out a very attractive advertising scheme calling attention to wires in general and "Crown" wires in particular. The advertising takes the form of an imitation of hand painting on porcelain of an attractive personality.

BALTIMORE COUNTY, MD. The county is now expending \$2,404 a year on its fire alarm system. Mr. T. W. Offutt, general manager of the Mt. Washington Electric Light and Power Co., has offered to carry on the whole thing in good shape for \$1,200 a year.

PHILADELPHIA NOTES

WASHINGTON, PA. The Washington Electric Light Co. are increasing their plant by the addition of a 200 h. p. Ball engine, built by the Ball Engine Co., Erie, Pa.

FOREIGN NOTES

GERMAN ELECTRICAL UNITS. The bill for the legislation of the ohm, volt and ampere in Germany has now passed through all its stages in the Reichstag. It has been amended to the extent of an "e" added to the word "amper," originally proposed.

The Electrical Engineer.

Vol. XXVI.

SEPTEMBER 8, 1898.

No. 540.

THE HARVARD POWER STATION OF THE BOSTON ELEVATED RAILWAY COMPANY.

BY H. W. WELLER, C. E., E. E.

INTRODUCTION.

THE steady growth of travel over the lines of the Boston Elevated Railway Company, formerly the West End Street Railway Company, has necessitated the construction of another large power station.

Owing to the marshy nature of the ground and the heavy character of the machinery to be installed close piling had to be driven to a depth of 35 feet under all foundations. The tops of the piles were cut off at a fixed level and a heavy bed of cement concrete laid to carry the foundations, which, of necessity, had

Switchboard Gallery.

Boiler Room.

View of Power Station.

Coal Pockets and Chimney.

Engine and Dynamo Room.

HARVARD POWER STATION, BOSTON ELEVATED RAILWAY CO., BOSTON, MASS.

This is located on the east side of Boylston street, in Cambridge, close to the Charles River and a short distance from Harvard Square.

to be very heavy and substantial, those for the chimney being of granite masonry.

The building fronts towards the Charles River, terminating

on Boylston street. It is 171 feet 8 inches long and is planned for a subsequent extension of 71 feet additional. The building is 125 feet 8 inches wide.

In a general way the buildings conform to the plan of the Dorchester Power Station, which was described in *The Engineer* of March 24, 1897, but are much larger. The engine room is in front and the boiler room adjoining it in the rear, with the coal-handling machinery and the stack behind the boiler room.

The buildings are of best selected hard-burned red brick, with granite water tables, cornices, sills and trimmings, and are built on concrete and stone foundations. The floor of the boiler room is about one foot above the level of the street and on a level with the basement floor of the engine room, and the floor of the engine room proper is about 12 feet above that of the basement.

The roof of the engine room is carried on arched steel trusses, supplied and erected by the Boston Bridge Company, and is of the special fire-proof construction adopted by the engineer of the railway company. It consists of a series of arches, composed of two layers of special flat fireproof tiles laid in cement, which arches are sprung from truss to truss. The tiling of the roof was constructed by Messrs. Guastavino, of Boston.

The system of coal pockets and trestle work was designed by Mr. C. F. Baker, the master mechanic of the railway company, and installed under his supervision. The coal is brought in cars, hauled by electricity over the tracks of the railway company from their main coal storage at the central power station at Albany

by a 4-inch Ashton pop safety valve, set to blow at a pressure of 175 pounds to the square inch.

The face of the setting in the front of the boilers is composed of white enameled glazed brick, making a very neat finish.

The boilers are provided with extension furnaces, which project about 8 feet from the fronts of the boilers, and are built of selected hard-burned brick, with a heavy lining of best fire-brick. The use of this extension is to give a larger combustion chamber and to prevent as much of the smoke as possible and utilize it for making steam.

The ashes are at present removed by hand and used for improving the adjoining property of the railway company.

All the feed piping and connections are of extra heavy brass, the water columns being of the reliance pattern fitted with high and low-water alarms. The feed water is admitted into the front of each drum, with the necessary stop and check valves. The blow-off piping is carried in a trench, covered with cast-iron floor plates, in the rear of the boilers.

Large doorways are provided in the boiler room wall opposite the boilers. The doors for these are hung vertically for convenience and are properly balanced with counter-weights.

The smoke flue from each boiler is connected into the main flue, as shown on the plan, and the gases are carried through a Greene economizer, furnished by the Fuel Economizer Company, of Matteawan, New York. The economizer consists of 56 sections, each containing 10 tubes, and aggregating 6,720 square feet

HARVARD POWER STATION, BOSTON ELEVATED RAILWAY CO. BOSTON, MASS.—PLAN AND SECTION.

street, and, being taken up the special inclined trestle and around the loop, is dumped into the bins in the rear of the boiler room. A track is laid underneath the bins or hoppers, and the boiler room charging cars of the C. W. Hunt make are run under the hoppers, filled by gravity, and are then run over the tracks right in front of the furnace doors. The coal is not shoveled from the time it is brought in ships alongside the dock at Albany street until it is shoveled from the cars into the furnaces. The storage capacity of the bins at Harvard is about 750 tons.

The boiler room is the same length as the engine room and about 56 feet in width. It contains three batteries, each of two 500 h. p. double-decked water tube boilers of the well-known Babcock & Wilcox type, making a total capacity of 3,000 h. p. at this time, and space is left for another similar battery, making a total of 4,000 h. p., which can be accommodated in the present building. The extension as laid out on the plans will admit of two more batteries, each of the same capacity, in the future. The roof is carried on straight steel trusses and has a monitor over the economizer. As shown in the plan, each boiler has three water drums, which are of open hearth steel 42 inches in diameter and 22 feet long, projecting through the front of the setting. Each drum is protected

of heating surface. Provision has been made for duplicating this machine with the increase of boilers which will be required in the future.

One possible objection to the use of the economizer is the floor space taken up, but in this case the objection is met by carrying the apparatus on iron columns and girders, leaving the ground space available to its fullest extent.

The economizer is connected with the stack by a square brick flue, and a by-pass flue with the necessary dampers is provided so that the economizer can be cut out at any time it becomes necessary.

Sufficient room is arranged above the economizer for proper inspection and cleaning, the top being reached by an iron stairway. The tube scrapers are operated from the line shaft of the power pumps, which are driven electrically.

Each boiler is provided with an individual damper in the setting, and the draft is also automatically controlled by a main damper, set vertically in the side of the stack and operated by a Locke damper regulator. An indicator in the boiler room continuously shows the position of this damper for the guidance of the men. The boiler room floor is of concrete, which presents a smooth and durable surface.

STEAM AUXILIARIES AND STACK.

The stack is 226 feet high and is built of selected hard-burned brick, with a 10-inch fire-brick lining extending for a height of about 50 feet.

The stack is octagonal in shape for about 40 feet, with molded corner brick and a granite plinth about 12 inches thick. The rest of the stack is circular, the outside diameter tapering from about 20 feet at the bottom to about 16 feet at the top, and finished off with a cornice and capped with a cast-iron cap made in segments and properly fitted and clamped together. The inside diameter is 11 feet. Two lightning rods of copper extend from the bottom to the top of the stack on opposite sides. These are connected underground to copper cylinders and at the top to a copper ring placed around the cap and carried on insulators. To this ring are connected four copper rods, tipped with platinum and extending to a height of 6 feet above the cap, thus forming a most efficient protection from the dangers of lightning.

The engine room is 170 feet in length by 66 feet in width, inside dimensions. It is built of selected hard-burned red brick, with granite sills and trimmings. It has 24 large sash windows on three sides and is therefore well lighted and airy. Large double doors are provided at each end of the room.

The basement floor is of concrete and level with that of the boiler room and has the necessary communicating doors with the latter. The pumps, condensers and heaters are placed in the basement. Iron stairways lead from the basement to the engine room at either end and also in the middle.

The feed pumps consist of three vertical triplex power pumps, 6-inch diameter by 8-inch stroke, driven by belts and shafting from a 500-volt electric motor. There is also one duplex steam pump 14-inch and 8½-inch by 10-inch stroke. This was supplied by the Deane Steam Pump Company, of Holyoke, Mass. The power pumps, being operated electrically, can be used to feed the boilers when steam is not available.

The engine room floor is laid with 4-inch spruce planking on iron girders and finished off with hard maple in narrow strips, and carefully polished and oiled.

Openings are left in the floor to permit of the pumps and condensers being seen at all times by the engineers on watch, and these openings are properly guarded by railings. Cast-iron floor plates are provided for easy access to the machinery and piping where necessary.

The engines and all steam and exhaust piping are covered with magnesia composition supplied by Messrs. Nightingale & Childs, of Boston.

THE ENGINES.

There are three engines, each of 1,800 h. p., nominal, with space in the present building for one more, while the proposed extension will have room for two additional, as shown by dotted lines on the plan, making six engines of a total nominal horse power of 10,800 as the ultimate capacity of the station.

The engines are all similar, horizontal, cross-compound, condensing, of the Corliss type, and are direct connected to the generators. The cylinders are 28-inch and 56-inch in diameter and 60-inch stroke, and the engines operate at a speed of 80 revolutions per minute. The flywheels are 24 feet in diameter and are built up in segments, rigidly bolted together, and are very massive, each weighing upwards of 60 tons.

The valve gear is an improved Reynolds-Corliss, the valves being placed in the cylinder heads to bring them closer together.

There is a reheater receiver between each of the high and low-pressure cylinders, and the piping, which is placed below the engine room floor, is arranged so that either cylinder may be run alone or run condensing or non-condensing.

The foundations for the engines are laid up in hard-burned brick in cement. The steam piping is specially designed and constructed for high-pressure work. It is extra heavy wrought-iron pipe and has cast steel fittings. The flanges are faced and grooved and corrugated copper gaskets are used in making the joints. The piping was furnished and erected by the engineers of the railway company. The main steam pipe is 14 inches in diameter and the connections from each boiler are 8-inch. All the valves are of the Walworth & Chapman flanged pattern for heavy duty, with outside screw and yoke, and each valve has a by-pass. All the main valves are controlled from the engine room floor.

A Reynolds separator is installed between the main steam pipe and each engine to remove the entrained water from the steam.

The feed piping is covered with magneso asbestos sectional covering, supplied by the H. W. Johns Company, of Boston and

New York, and is neatly finished off with polished brass bands. The condensers are of the vertical independent jet type, Reynolds pattern.

The exhaust piping is 20 inches in diameter and is provided with an automatic relief and stop valve of the Reynolds patent to permit of a free exhaust into the atmosphere in case of any interruption in the operation of the condensing apparatus.

The oiling system is a combination of pressure and gravity and is very efficient. The engines were built and installed by the E. P. Allis Company, of Milwaukee, Wis.

There is a traveling crane of seven-ton capacity, supplied and installed by the Boston Bridge Company. It runs on girder tracks built into the side walls of the building.

THE GENERATORS.

There are three direct connected 12-pole compound-wound generators, each of 1,200 kilowatts capacity, with cast steel frames and pole pieces. They were manufactured and installed by the General Electric Company. Each field spool is arranged with separate spaces for the shunt and series windings. The series coils are wound with flat strips of copper, while the shunt coils are composed of the usual round insulated copper wire.

Series bars are attached on one end to the series windings on the two lower spools, and on the other to slate blocks screwed to the frame of the generator.

An adjustable shunt is placed across one end of the terminals for regulating the compounding of the machines. This shunt is very long, and is held in place by a stand with insulated supports for the shunt to rest on. The brush leads consist of a number of lengths of flexible insulated cable, which are brought to slate blocks attached to the frame. Insulated copper rings are used for connecting the positive and negative brushes, respectively, together. An adjustable brush holder yoke allows all the regulation of the brushes that is necessary.

The armatures are built up of laminated disks of soft iron dovetailed into the spider and held in place by large cast-iron rings bolted securely together. Slots are cut in the discs, in which the winding is placed. This consists of the well-known barrel type, with four bars of flat insulated copper laid in each slot and soldered together on the flywheel side, the change and connections being made on the front, where flexible leads connect the windings to the commutator. Wire bands on the core and adjustable copper bands on the ends hold the windings in place.

Each frame rests on two foundation plates, and these in turn are bolted down on the capstones. On each end of the plates a shoulder is cast to prevent possible movement of the machine in case of trouble.

The frames are insulated from the foundation plates by maple blocks.

Three 1,000,000 c. m. cables connect the positive side of the generators to the switchboard, and the same on the negative side. Kicking coils are placed in the positive cables and the positive leads on all generators are the same length to ensure perfect regulation. Suitable equalizing switches are placed near the generator.

THE SWITCHBOARD.

This is placed on a raised gallery on the west side of the engine room, where all the machines are in sight. It is composed of thirteen feeder panels, three generator panels and one station panel.

Each feeder panel carries two feeders and has the necessary ammeters, switches and circuit breakers.

Each generator panel has a 5,000-ampere circuit breaker and ammeter, a 3,000-ampere double-pole switch and the field rheostat controller.

The station panel has on it a spare rheostat, which, in case of trouble, can be quickly connected. It also contains a 10,000 ampere total ammeter, lighting switches, the necessary station voltmeter and also a duplicate for use in case of accident to the other. The panels are of the standard General Electric make and the volt and ammeters are of the Weston type. A recording wattmeter of the General Electric make is also provided.

On the board is an automatic alarm, which, when a circuit breaker trips, rings a bell, which can be heard all over the station. Another and very novel feature designed by Mr. C. F. Baker, the master mechanic, is an arrangement to relieve the other generators of an excessive load should one unit be cut out of service quickly from any cause. Attached to each generator circuit breaker is a plug, which, when the breaker is tripped,

makes contact with one terminal of a small storage battery, the other terminal being connected to magnets directly under the armatures of the feeder circuit breakers. These magnets are strong enough to open each feeder breaker. The number of feeder breakers tripped is controlled by using a plug board with enough plugs inserted to trip enough circuit breakers to equal the load of the generator shut down. There is also a bus-bar in the rear of the switchboard, to which, by the use of a jumper, any circuit breaker can be opened and the load thrown to some other feeder board. Every precaution has been taken to prevent the shutting down of the station. A Bristol recording voltmeter and Crosby recording steam gauge are installed in the office, keeping an accurate record of the voltage and steam pressure for reference.

At one side of the switchboard gallery is the office of the chief engineer, below which are the various bath and toilet rooms for the use of the men.

The station is in charge of Mr. T. W. Teale, chief engineer, assisted by A. A. Warner, A. O. Fletcher, T. H. Kimball, G. W. Berwick, J. B. Libby, J. Thompson and A. E. Smith. Mr. M. Davis keeps the boilers in condition, with J. McCarthy, C. H. Breadmore, J. Tutts, J. Wright, J. M. Burley and H. K. Webber as firemen.

In conclusion, the writer desires to thank the various officials of the company for their courtesy and assistance, especially Mr. C. F. Baker, the master mechanic, under whose charge the station and its machinery were designed and erected.

Herrick's Electric Car Inspection System.

BY A. B. HERRICK.

THE mechanical maintenance of street railway equipment is amenable to visual inspection. The causes for mechanical depreciation are strains, friction and vibrations, and the remedies for them can be easily applied, but the electrical part of an equipment depreciates from other causes, such as heating, from overloading the motors, lack of equalization between motors, the improper use of the controller by the motorman, and many other causes, but the effects are not necessarily visible and they are ordinarily only remedied after a breakdown has occurred. The inventor of this system, after examining into the cost of electrical repairs in a number of car barns, found that a large part was chargeable to the time taken to locate them, and often in dismantling the equipment to find them, and the repair was made on the broken-down part, whereas the primary cause of the breakdown had not been remedied.

As it is of more interest to cite examples than general principles, in one case where this testing system was applied an armature winder had been discharged, who, from samples of his work, was certainly an excellent winder and insulator. As soon as the test was applied to the equipments burnt out fields were found, and in 46 equipments 35 burnt out fields were discovered and replaced with good fields. Since that time there has been no trouble with armatures. Another case could be cited where the trouble being in the rheostat, the power consumption had crept up .4 of a kilowatt per car mile. Here the rheostat on the equipment had increased in resistance to such an extent that the car would not start until the third notch had been reached. During the passing to the third point the car was standing across the line consuming energy with useless results. Putting in proper rheostats showed marked increase in efficiency in the kilowatts taken per mile operated.

The electrical repairs are one of the uncertain features in car barn expenses, and the breakdowns and crippling occur when the equipments have been forced by extra service and their continuous operation would be of the greatest value. Again, it is well known that certain equipments are continually in trouble, while others operate continuously at little or no expense, and it seems to be an element of luck or chance whether an equipment can be operated continuously or not from an electrical standpoint, and yet all these equipments are uniformly equipped and should operate equally well. Still there is some reason why certain equipments in the same class do not give equally satisfactory service, and it is for the purpose of maintaining to a standard and making equipments uniform in their service that the "Herrick Electrical Inspection System" has been devised in order that these electrical inequalities can be made visual and be repaired. The cost of these electrical repairs as now carried out is abnormal and out of proportion to the revenue obtained from the operation

of the equipment, and to bring out this cost clearer, in two cases which I have investigated the cost of electrical repairs of the equipment per car mile was in excess of the repairs per car mile of a 100-ton freight locomotive on the Pennsylvania Railroad.

It has been proved that by changing the car barn to a maintenance shop where the equipments can be brought up to a uniform standard electrically and kept there, rather than a place in which the cripples are repaired, decreases the cost of maintenance per mile and largely increases the reliability of service rendered. The Herrick testing system is devised as a method of locating any of the equipment troubles before they develop into breakdowns and render the equipment inoperative. The reliability of the system is such that in several shops where this system is used the inspector will write out the order for the electrical repair of the car without having seen it.

THE HERRICK ELECTRIC RAILWAY TESTING SET.

The system has been carried farther than the inspection of the equipment only. The set can be used in the winding room for locating faults in armatures, fields and rheostats, and also controllers and commutators, all necessary appliances and terminals being furnished by which these tests can be quickly and readily made, and all new work and repair work can be tested to see that it has been properly done and is up to standard.

This testing set can be put on the equipment and run out on the road, and equalization tests, power consumption, line losses, ground return losses, bond losses, electrolysis tests can be made; in fact, the set comprehends within itself every test necessary in the railroad business, and the tests and methods selected for these various tests have been the outcome of years of practical experience.

It was found that when the complicated connections were left in the hands of the inspector false results were obtained by misconnections and the instruments were burned out. To reduce this method to the simplest system possible all these terminals

are brought behind a rotating interlocking dial and so laid out that only the proper receptacles are exposed for the terminals for that test when that test registers behind a pointer, and all the connections are permanently made inside the test case. This method avoids the possibility of misconnections and burn-outs and reduces the system to the simplest methods possible, so that anybody competent to make a mechanical inspection is capable after a short period of instruction of making and interpreting all the results.

Two special shielded Weston instruments are used, which are

adjusted as milliampere and amperemeter for the main current. The other instrument is both a volt and ohmmeter and has four ranges of voltages for full scale and three ranges when reading ohms direct as an ohmmeter and one scale reading megohms insulation, besides the calibrated rheostats used in the inspector's tests. Every effort has been made so that the inspection test can be quickly made, and a complete inspection of an equipment need not take over three minutes where everything is provided for making these inspections.

THE CROSS-COUNTRY ROADS AT CLEVELAND, OHIO.—I.

BY C. B. FAIRCHILD.

INTRODUCTION.

Soldiers' and Sailors' Monument, Cleveland.

The terms "suburban" and "interurban," as commonly used, are not names entirely applicable to five long electric high-speed railways that reach out in as many directions from Cleveland, and which are each outlined on the accompanying map. The lines, aggregating a combined distance of 156 miles outside the city

limits of Cleveland, have linked the name of the city more prominently with this class of roads than that of any other city of the country. The term "suburban" carries the idea of an overgrown street railway, and "interurban" is a run of the same class of cars between two neighboring cities, but as these are not the conditions which are found in the roads which it is the province of this article to describe, the term used for the title of this story seems more appropriate.

This class of railways is distinct from all others; it is true, they have wheels and rails in common, but in function, equipment, speed and management there is a glaring contrast, and they require for their inception, construction and control an otherness of intellect from that found in ordinary street railway practice. They do not seem to be in their origin either inventions or discoveries, but rather creations, and that from an *à priori* source, for they were not founded on either observation or experience and did not seem to come in answer to a demand, but have grown up and have proved a financial success beyond the most sanguine expectation of the pioneers and promoters; indeed, they have produced new and independent results in the region of both material and social science. Now that they are here, and not mere problems, and their worth appreciated, both by patrons and investors, and because they are suited to a great range of conditions, people everywhere will want and accept them, so there is no question but they must multiply indefinitely, and if so, it will be of advantage for all to know their origin, condition, experience, standards and results, which have become positive and certain and will serve as a basis for those contemplating similar enterprises without having to repeat the experimental stages.

The general conditions as they exist in this locality are one large central city (Cleveland, having an estimated population of 375,000), surrounded by a rich farming country, with outlying villages and small cities within a distance of thirty-five or forty miles. It is claimed by those experienced in the construction and management of these lines that roads between cities of about the same size and character will not prove as successful as when there is one city sufficiently large to attract shopping by its business advantages and in turn supply a large pleasure traffic. Other

conditions may vary widely, as they do in the case of the five lines herewith described, as each will be seen to have its peculiar characteristics.

The cars of all the cross-country lines enter the city over the tracks of one or the other of the two local companies, and the latter furnish the power, man and operate the cars, except in one case, collect the fares both ways inside the city limits, and pay to the former a royalty on a mileage basis for the use of the cars

PRESIDENTS OF THE CLEVELAND, O., SUBURBAN ELECTRIC RAILROADS.

A. H. Pomeroy, Pres. Cleveland, Berea, & Oberlin R. R.	C. W. Wason, Pres. & Gen'l Mgr. Cleveland, Painesville & Eastern R. R.
H. S. Everett, Pres. Akron, Bedford & Cleveland R. R.	W. A. Taylor, Pres. Cleveland & Chagrin Falls R. R.
B. Mahler, Pres. Lorain & Cleveland R. R.	

within the city limits. All the outlying lines operate long double-truck cars, which run single-ended and are vestibuled, and are usually divided into two compartments, one for the accommodation of smokers or for the reception of freight and express. All the cars make loops and pass the Square and Soldiers' Monument, in Cleveland, near the centre of the city, shown at the head of this article, and at the outer ends are turned on "Y's" or loops. Each of the companies, with one exception, provides its own agents for handling the freight and express; that of the other company is handled by the agents of the Amer-

ican Express Company, with the exception of the milk traffic.

Five companies control the six lines of road, and of these three are closely allied, being controlled by parties that are interested

At this stage of development the Christy Brothers, of Akron, O., since prominently identified with a number of these roads, became interested in the enterprise and undertook to interest

financially in each of the others. So here is the story as we find it to-day, the lines of each company being described in the order of their origin.

Cleveland, Berea, Elyria & Oberlin Ry. Co.

Tappan Walk, Campus, Oberlin College.

BEREA is a small city located about ten miles to the southwest from Cleveland, has a population of about 3,000, and here, in 1893, existed a small street railway, on which one one-horse bobtail car was operated between the hotels and depot. This line was owned by Mr. H. A. Pomeroy, cashier of the local bank, and a few associates, and during the year noted he and his associates were induced to lay a line of track along the highway to the city limits of Cleveland. What the motive power was to be does not seem to have been decided, but it was a question

between dummy engines, storage batteries and overhead trolley. The financial depression of the same year called a halt in the operations, and the company were induced to exploit with the Ford & Washburn storage battery, and this company began the operation of a storage battery car between Cleveland and Berea during the winter of 1893 and 1894, and during the few months' run carried over 12,000 passengers, or enough to demonstrate that there was a paying patronage to be had over the line. This encouraged the owners, and, while they did not see fit to adopt the storage battery system, they were induced to provide sufficient capital to put up the overhead equipment.

Cleveland capitalists in the scheme, but were turned down with more or less ridicule by the very persons now most largely interested in this class of roads. Nothing daunted, however, they returned to the Berea people, and enough capital was secured to equip the road with second-hand cars and motors and second-hand power station equipment. In May, 1894, the line was completed. A paying patronage at once developed, and capitalists

QUARRY SCENE NEAR BEREA, O.

began to discover the advantages to be had in this line of investments, and responded freely to calls for funds for extensions and improvements, so that in the following year (1895) the line was extended from Rockport to Elyria, a distance of seventeen miles. A new power station, with new equipment, was erected at Rockport, with power shops and repair shops adjoining, and during

the past year the line has been extended to Oberlin, an additional distance of nine miles, making the total distance from the city limits of Cleveland to Oberlin thirty miles, and, counting the distance from Rockport to Berea, gives a total distance of thirty-six miles. The company are now engaged in laying a double track four miles outside the city limits of Cleveland, and the roadway is being paved with brick by the county authorities.

The headway on each branch is one hour, so that the cars leave the Public Square in Cleveland every half hour and run over the same tracks as far as Rockport. The schedule time between Cleveland and Oberlin is two hours and ten minutes and between Cleveland and Elyria one hour and forty minutes, and between Cleveland and Berea one hour and fifteen minutes. The average

ROCK RIVER POWER HOUSE AND CAR HOUSE, C. B. E. & O. R. R.

speed is about twenty-five miles an hour, but in places a maximum speed of forty miles is reached. The fare for round trip to Oberlin is \$1.10, or 60 cents one way. The round trip to Elyria is 85 cents and 45 cents one way, while to Berea the rates are 45 cents and 25 cents. These rates include a transfer to the lines of the Cleveland City Railway within the city limits. Tickets are sold and the cars are worked outside the city after the manner of steam passenger traffic. The company provide waiting rooms at the terminal stations, with a ticket office and an agent, while at Elyria tickets are sold from the hotel offices.

The express matter is handled at present by agents of the American Express. The milk traffic, which has increased to considerable proportions, or to an aggregate of about 1,000 gallons per day, is handled by the company on a special car, and this is scheduled to leave Elyria at 5 o'clock mornings and evenings. The charge for handling the milk is 1 cent a gallon from stations as far as Elyria; from points beyond a charge of 1½ cents is made. There is no charge for returning the cans. The milk stations at farmhouses and crossroads are provided with platforms to facilitate loading. The trade in this line has been entirely built up by the coming of the electric cars, as many of the farmers, who, for the most part were formerly engaged in the raising of grain or general farming, have been induced to buy cattle, and so have instituted a line of dairy farming.

The region over which the line passes is uniformly level and the road is through one of the richest farming regions in the State, and is bordered on either side by comfortable farmhouses always within sight of each other, and in many cases having lawns with beautiful flowers, while they are surrounded by venerable shade trees of maple or elm, and frequently of gigantic size. There are also extensive orchards of apples and pears, and the landscape, from the diversity of products, including wheat, oats, corn and grass, presents a panorama of ever-changing and beautiful colors, backed frequently by a dark green outline of forests that are left to grow at the rear of the farms. Truck farms and vineyards are not wanting to make up in attractive features, while there are also a few stock farms for the raising of blooded horses. The terminal cities and villages through which the lines pass of course help out with their patronage, the most westerly of which is Oberlin, an especially attractive village, it

being the seat of the popular college of the same name, which has an attendance during the school season of from 1,300 to 1,500 students of both sexes. The college buildings are twelve in number, many of them of modern design, and all located in or near the campus, which is a beautiful, shaded tract in the heart of the village. Elyria, the county seat of Lorain county, is a thriving little city of nearly 10,000, and furnishes a large traffic for the line.

Berea is also the seat of two popular schools, one known as Baldwin University, the other the German-Wallace College. There are also in this locality numerous stone quarries, from which much of the fine Ohio sandstone for building purposes is obtained, also flagging for sidewalks and curbs. The large flagging blocks are also used to some extent for paving the street, and these two towns, Berea and Oberlin, can probably boast of the largest paving blocks to be found in the streets of any city of the country, as they are found three and four feet square, and sometimes as much as 3x6 and even up to 4x8 feet. They are not popular, however, and are being replaced by modern brick paving.

ROADBED AND OVERHEAD CONSTRUCTION.

The line for the most part runs along the highway just outside the wagon path, but in some cases in order to cut off a long curve it is located for a few miles on private right of way through the farms. The route being generally level, only a little grading was required; the roadbed is slightly turnpike to provide for drainage. Only on the new extension between Elyria and Oberlin is any extensive filling required, and on this extension the roadway was widened to provide for the track, the farmers giving to the company a border all along their holdings. The culverts and underground work where required are all of solid masonry and steel girders, no woodwork being employed. In the more recent construction a 60 and 70-pound tee-rail of the Shang-high type was employed and the joints are thoroughly bonded. The ties are placed two feet apart and thoroughly tamped. The tracks, notwithstanding the severe service and high speed, are standing up exceedingly well.

The trolley and feed wires are supported for the most part on wooden side poles with brackets. Turnouts are provided at suitable intervals, and these are equipped with spring switches and block signal lamps. There is also provided at each turnout a telephone station, through which the conductor of each car reports to the starter as his car arrives. At all steam railway crossings derailing switches are located, at which the conductor is obliged to go forward and throw the lever before his car can cross. This is a provision established by State law for all the street railways, and usually within the city limits the levers with

COMBINATION CAR, C. B. E. & O. R. R.

which the switch is thrown are attached to the side of one of the trolley poles.

At Rocky River the line crosses the deep canyon over a steel truss bridge 1,200 feet in length and 140 feet above the roadbed. This is a county bridge, and for the privilege of crossing the company contracts to provide electric lights for illuminating the bridge and also for keeping the roadway clean.

POWER PLANTS.

The power for operating the entire system outside the city limits of Cleveland is generated in two stations, one located at

Rockport and the other at Elyria. The Rockport station was first erected, and the building is a brick structure with an iron smokestack. Near it is a long brick building for car house and repair shop, in which are also offices for the train dispatcher and superintendent. The steam is generated in Stirling water tube boilers of 900 h. p., and the power equipment consists of two Allis-Corliss simple en-

JOHNSON No. 34 50 H. P. MOTOR, C. B. E. & O. R. R.

gines, each of 350 h. p., and which drive by means of leather belts two Westinghouse generators of 250 kilowatts capacity.

The Elyria station is a wooden building, and the equipment consists of Stirling water tube boilers of 550 h. p. and two simple engines manufactured by the Slater Engine Company, of Warren, Mass. These have cylinders 22x42 inches, and are run at ninety revolutions, with a 17-foot flywheel weighing eighteen tons, with ball governors. These are each belted directly to a Walker generator of 250 kilowatts capacity. The auxiliary steam equipment consists of Berryman heaters and Ludlow Dun pumps. There is also a pump for fire purposes. The switchboard, with the exception of the meters, is equipped with Walker instruments. The feeders from both stations are coupled together and the current leaves the station at a tension of 650 volts, and the distances to which the current is carried from the stations are four, six, seven, nine and ten miles. The stations also provide for their own lighting.

ROLLING STOCK.

The present equipment consists of sixteen double-truck cars, which were made by different builders; eight of these, however, were bought new this season and were manufactured after designs furnished by the company by the G. C. Kuhlman Co., the well-known car builders of Cleveland. These cars embody all the latest improvements that could be suggested by either the managers or builders, and embrace the combined experience

8 feet 5 inches outside. These are finished with a coach type of roof, with the deck lights arranged in sections and operated by an original arrangement of worm and gear attachment.

The special features which distinguish these from some other make of cars are the arrangement of the braces and truss bars, which effectually prevent the body from humping in the centre and the vestibules from sagging. The window lights are of plate glass, with Forsyth shades. The interior finish is of cherry, with decorated bird's-eye maple ceiling. The seats are covered with rattan, are extra large and of the Hale & Kilbourne type. Each car is provided with a toilet closet and an icewater tank. The floors are double, with an air space to provide for warmth. The exterior is painted in bronze green, with special bronze trimmings, and decorated and lettered in gold, and all are provided with Meaker registers. Five of the new cars are mounted on extra heavy No. 15 trucks of the Peckham type, while the other three have trucks made by Dorner & Dutton, of Cleveland, the company now being known as Van Dorn & Dutton.

The Peckham truck is shown in the accompanying illustration, and is said by the management to be entirely satisfactory as to strength and ease of adjustment on curves. Some of the special features embodied in these trucks are that two sets of bars compose the middle of the side frame, which are placed apart to permit the swinging of a nest of half elliptic springs between them. The bolster is built up in truss form of two flat bars of a thickness and width suitable for the car bodies to be carried. These bars are carried by adjustable posts. Secured to the top bar of the bolster are "King" side-bearing springs to provide for a slight rocking motion of the car body. The bolster is supported at each end on one or more half-elliptic springs, depending on the weight of the car body to be carried. The ends of these springs are carried in universal M. C. B. links, which permit of a motion both longitudinal and transverse with the axis of the truck, thus permitting the span of the springs to increase as the load comes on them, and at the same time acting as links providing for the transverse swinging of the truck bolster. These links are supported upon the side frames by coil springs, making three separate sets of supporting springs; i. e., the bolster half-elliptic, the bolster link coils and the journal box coil springs between the car body and rail.

The top bolster is guided between the upper bars to prevent motion in a direction longitudinal with the car body. These guides serve to transfer the draft of the motors from the trucks to the car body. The location of the half-elliptic springs between the bars of the side frames permits the drawing down of the bolster to the narrowest permissible width, thus shortening the wheel base of the truck. This location of the elliptic springs also imparts to them the properties of an equalizer, permitting any of the wheels to rise independently of the car body and supplementing in this direction the action of the yoke springs, located directly over the journal boxes. The motors are sup-

NO. 15 PECKHAM TRUCK, C. B. E. & O. R. R.

had from the operation of this class of roads in this region, and, like the deacon's one-horse shay, they are as strong anywhere as in the weakest parts. Five of these new cars have smoking compartments, and the other three compartments for baggage and express. The interior of these, however, have the same finish as the main portion. The length of these new cars over buffers is 43 feet 6 inches, the bodies being 32 feet in length, and in width,

ported upon the transoms, which are rigidly secured to the side frames of the truck, which in turn are provided with corner brackets or braces to keep the truck in alignment. The wheel base is only 5 feet 8 inches for motors.

The new cars are equipped with Johnson motors, No. 34, 50 h. p. type. Some of the cars have a double equipment of motors, one a triple and one quadruple equipment, and from tests re-

cently made the company has decided to make the three-motor equipment a standard, as this number suits the conditions better than the two or the four-motor equipment, and all the cars are to be equipped in this manner. It is claimed that this is the only high speed road in the country operating a three-motor equipment with a suitable controller.

AIR BRAKES.

The entire equipment of double-truck cars, sixteen in number, is provided with air brakes of the Christensen independent motor compressor type. These brakes have replaced on some of the cars the axle-driven type of compressors made by the same and other companies, the high speed being too much for axle-driven compressors. The motor compressor in this case is placed in the vestibule, and these are to be provided with an automatic starting and stopping apparatus. The operation of the air brake equipment is very satisfactory, and the air whistles in connection therewith are considered almost a necessity on this class of cars.

TRAFFIC AND MANAGEMENT.

The number of passengers carried during the year 1897 was 557,000. The income from this source, together with that from the freight and express, is a gratifying return for the money and skill invested. Mr. A. H. Pomeroy, of Berea, is president of the company; A. E. Atkins, of Cleveland, vice-president; L. E. Meacham, secretary, while the active management of the operation is in the hands of Mr. F. T. Pomeroy, treasurer and general manager, with offices at 614 Garfield Building, Cleveland.

Cleveland, Painesville & Eastern Ry. Co.

THE main line of this system, which extends in a northeasterly direction from Cleveland to Painesville, a distance of thirty miles, was the third of this class of lines to be built leading into Cleveland. The parallel branch, or Shore Line, which extends from Cleveland to Willoughby, a distance of 18 miles, parallel to the lake shore and between it and the main line, was

Long Trestle.

SCENES ALONG ROUTE OF CLEVELAND, PAINESVILLE & EASTERN R. R.

Two snow ploughs, manufactured by the Taunton Locomotive Works, Taunton, Mass., complete the rolling stock equipment, and these serve to keep the line open through the severest storms.

the most recently constructed of all, having been opened for traffic April, 1898. Both routes are through a farming region which is almost level, the total rise at any point not being over forty feet and none of the grades is over 4 per cent. Both lines

have their particular, attractive features, which differ in many particulars from those before described, and both parallel the lines of the Lake Shore & Nickel Plate Road. On leaving Cleveland the routes for the most part are along Prospect and Euclid avenues, the latter being noted as one of the most beautiful residence avenues to be found in the country, it being bordered to a great distance with handsome houses and beautiful and attractive grounds.

While the line is through a farming region principally, there are on the main line a number of small villages such as Euclid, Wickliff, Willoughby, West Mentor and Mentor, and it terminates at Painesville, a city of 5,000 inhabitants. At Mentor the line passes in front of the Garfield residence, which is still occupied by Mrs. Garfield, wife of the late President. To the south of the line the land rises gradually for a considerable distance, and the grade terminates in a ridge on a line with the road, which is about 200 feet above the lake and which is crowned at intervals for a number of miles with the palatial homes of some of the country's notable millionaires. The line passes in front of Wade Park and past Lake View Cemetery, in which stands the Garfield Monument, a landmark for all this region. The Shore Line runs in sight of the lake for the most part, and a portion of the route is over private right of way. Extensive vineyards border the line on both sides, which near the city are interspersed with truck farms. There are also numerous greenhouses, and on both lines several noted stock farms.

The Shore Line passes in close proximity to Gordon Park and to other parks on the lake shore, one of which, known as Willoughbeach Park, embraces twenty-five acres and is owned and controlled by the railroad company, and is being improved and beautified and provided with suitable pavilions, making it a very attractive resort about fifteen miles from Cleveland. On the Shore Line a new steel viaduct is being erected, the cost of which will be about \$50,000, and which is borne jointly by the Lake Shore & Michigan Southern Railway Company (whose tracks the viaduct crosses), the Cleveland, Painesville & Eastern Railway Company and the village of Collinwood. The tracks of the main line also cross a number of bridges and trestles, one over the railroad tracks being shown in the accompanying engraving, and a bridge over the gorge of the Chagrin River at Willoughby, which was built by the railroad company at a cost of \$50,000 and which, with the exception of the portion over the channel of the river is of timber construction. The bridge proper is of steel plate girders, reinforced by heavy truss girders above, and was constructed after designs and with equal strains as for the bridges on the neighboring steam railways.

The headway on the main line is one-half hour, and it requires two hours to make the trip between the squares of the two cities. The schedule speed is thirty miles per hour, including stops and the cars are frequently run at a speed of forty miles per hour. On the Lake Shore branch the headway is one hour except on Saturday and Sunday, when it is one-half hour. The through fare is 45 cents and 80 cents for round trip, and 25 cents each way to Willoughby, on the Lake Shore branch.

The fare in the city limits is collected by the conductors of one of the city lines, which pays the railroad company on a mileage basis. In collecting the fares outside the city limits the conductor issues a record ticket to the passenger, which is torn off from his book by means of a metal square, the stub indicating the amount received and which serves as a means for checking the conductor. The cars are provided with the Sterling registers, but they are only used by the city conductors.

ROADBED AND OVERHEAD CONSTRUCTION.

The tracks between Euclid and Painesville are single and are located beside the highway and are laid with an 8-inch 68-pound rail, Wharton girder type. These are bonded on the under side by bonds made by Washburn & Moen. Gravel ballast is provided throughout the entire length.

Two trolley wires are employed of the figure 8 type and are equivalent to No. 000. These are supported by span wire construction except at the bridge and trestle, where brackets with flexible hangers are used. The span wires are 5-16" seven-span galvanized iron wire cable, tightened by bolts and insulated by 2½-inch globe strain balls. The trolley wire is hung with mechanical clips made by Hursburgh & Scott. No soldered hangers are used and the strain ears are fastened by rivets. The advantages of a double trolley construction is that temporary repairs may be made more easily, and if one wire should be broken it does not disable the line.

The feed wires, three each, extend in both directions from the power station. The first feeder running east ends and taps into the trolley at a distance of about four miles from the power house. By this arrangement the voltage near the power house is as low as at any other point, and which ordinarily would be too high, as the current leaves the station at a voltage of 700. The second feeder extends for about two miles farther, and the third to the end of the line, and both are tapped into the trolley every 1,000 feet. The same arrangement is followed to the west.

The wires for operating the company's telephones are also carried on the poles, or, in case there are trees in the way, the telephone wires are supported by the span wires. The cars are stopped only at stated points, and at these places a platform and waiting bench are placed and each stop is numbered. These stations are about 700 feet apart in the villages and 1,400 feet apart along the country road.

The tracks of the Willoughby branch, which, as noted above, was the last of this class of roads to be erected, are constructed after the best steam railway practice. The soil, which is sandy, is turnpiked, and the entire line is ballasted with gravel, which was brought in from gravel pits owned by the company, and which cost for this branch alone over \$20,000. The ties are a little heavier than those described for the main line and spaced two feet apart. The rails, which are of the American Society of Civil Engineers' standard T-pattern, are of 73-pound section, and are rolled in 60-foot lengths, being bonded and connected as described for the other lines, except that the angle bars are unusually heavy, and the nuts with which the bolts are fastened are placed inside of the rails to facilitate inspection by the track-walker. The overhead construction is like that described for the main line.

Stopping places are numbered and noted by signs attached to the side poles, and at important stations small lean-to houses are provided for shelter with open fronts, it having been found by previous practice that open front stations are more desirable, for the reason that if they are enclosed and provided with doors they become a rendezvous for tramps and undesirable persons, who are apt to leave them in a filthy condition.

The sidings are of ordinary lengths and are provided with spring switches, as described for the other lines, all of which were furnished by the Cleveland Frog & Switch Company. A portable telephone is carried on each car, and at the distance of a mile along the line taps from the telephone wires are brought down to two stiff wire loops in hoods which are attached to the poles about ten feet from the ground. The 'phone is attached by means of a pole and flexible cord. By this means the conductor can call up the office at Willoughby and at either end of the line. No call bell is carried, however, on these car 'phones, so that while the car may call up the office, the office cannot call up the car. A small telephone exchange is located in the office at Willoughby, with wires to both ends of the line to the barn, power house and the residence of the operating officers. It is stated that it would be almost impossible to operate this class of roads in safety without the use of the telephone.

POWER STATION.

The power station, main car barn, the repair shop and operating offices of both branches are located at Willoughby. The latter occupy a small dwelling which has been converted into railway offices and which fronts on the main street, near which the line turns and behind which stands the car house. The car house and repair shop are of brick and under one roof separated by a fireproof wall. The power for operating the shop tools is obtained from a 5 h. p. motor. There is one repair pit, and located within this on a small track an hydraulic jack for handling the armatures. An overhead crane provides for handling heavy parts. In the car house are three tracks, each of which is of sufficient length to accommodate three cars. There is also a small car house at Painesville, where one car is always left over night, and at Nottingham, on the branch line, is also a car storage house, which is of brick, with a single track; foundations are provided, however, for duplicating the structure. The waiting station and an oil house stand near this structure.

Among the special machines constituting the repair shop equipment is a motor air compressor of the oscillating type, which was manufactured by the G. E. Company. This compressor provides air under pressure, which is utilized for cleaning the car cushions. It is conducted by underground pipes to different points in the yard and shop by means of a suction cleaner manufactured by the Chicago Pneumatic Tool Company.

The dust is readily removed from plush cushions under a pressure of about 40 pounds. This is considered a very desirable auxiliary as a means for cleaning cars.

The power house is located a little east of the town in the valley of the Chagrin River and about one-quarter of a mile from the track. This valley is crossed by the long wooden trestle bridge noted above. The coal is delivered from the Nickel Plate Railway by way of a siding and trestle to the top of the building, the latter, as before noted, being in the valley, where the coal is dumped into the main hoppers, which occupy a space above the boiler. From these hoppers coal is drawn into vertical chutes which are attached to a weighing scale, and each charge is weighed on its way to the boilers. There is also an arrangement of tanks, in which the feed water can be weighed when tests are to be made.

The steam equipment consists of four Stirling water tube boilers manufactured by the Stirling Company, of Barberton, Ohio. These are each of 250 h. p. capacity and are equipped with Murphy stokers and settings, built by the Murphy Iron Company, of Detroit, Mich. In the stokers the coal is partially coked, so that the combustion under the boilers produces very little smoke. The auxiliary steam equipment consists of pumps made by the Dean Steam Pump Company, of Holyoke, Mass., and the condensers and feed water heaters are manufactured by the manufacturers of the engines.

The power equipment consists of two direct-couple units of 250 h. p. each and one of 500 h. p. The engines, which were built by the C. & G. Cooper Company, Mount Vernon, Ohio, are cross-compound, condensing 90 and 100 r. p. m. The two multipolar 200-kilowatt generators and one multipolar 500-kilowatt generator are of the General Electric type and are wound for a voltage of 700. The engines are fitted with single eccentric rings on the high-pressure cylinders and double eccentric on the low. There are two governors. One operates the throttle valve, the other releases a weight, which in turn operates a butterfly valve, cutting off steam whenever the speed is above a predetermined rate and at the same time operates a throw-out switch. The piping is so designed that either cylinder may be run by live steam independently.

ROLLING STOCK.

The car equipment is all of the J. G. Brill manufacture, and comprises thirty cars, six of which are open cars, five of them employed as trail cars, while the sixth is equipped with motors. The cars are 40 feet over all, handsomely built, and are modeled after steam railway practice. The closed cars were originally built with a single compartment, but more recently a partition has been erected to provide for a smoking compartment. The partition as well as the ends of the car are provided with sash and lights, giving a full view in either direction. The seats in the closed cars are of the steam railway type and provide for forty-two passengers. Some are upholstered in plush and others in rattan. The latter material is considered preferable, as it is more easily kept clean, and when stained can be restored by the use of an enamel paint. The open cars seat fifty-two people.

The roof structure of the open cars is of birch panelling, the alternate strips being stained cherry color. The carlins are exposed and are unusually heavy. Four six-inch ventilators have been added to the closed cars by the company. These pass through the ceiling and terminate in an ornamental crown above the roof. These provide for suitable ventilation during cold weather, when the passengers object to having the doors open. The ventilators are manufactured by the Star Metallic Ventilator Company, of Philadelphia. For illuminating purposes the cars are equipped with twenty incandescent lights in four circuits, two being placed in the sign case on the front dash. The object of two is to provide light in case one should fail. A lightning arrester is placed in the lighting circuit, together with a choking coil about 18 inches in length. These are located under the hovel in the vestibule. Circuit breakers are also placed in the hovel of each car in connection with the switches. The headlights are of the largest size, such as are employed on steam railways.

The cars are all mounted on Brill No. 27 trucks and are equipped with four No. 57 or 50 h. p. G. E. motors. The cars were originally equipped with two 75 h. p. motors, but the four-motor equipment is found to be preferable for high speed and for quick acceleration. Electric brakes are provided on all the cars which are regarded as very efficient and are economical to maintain, the expense for the renewal of brake shoes being much less than with ordinary brakes. The wheel brakes, however, are re-

tained, and are used when it is necessary to bring the car to a standstill on grade, as the electric brakes, which are operated by current generated by the motors, are released when the wheels come to a full stop. As the wheel brakes are used very little, the head and shoe are cast in one piece. The wheels are 33 inches in diameter and were manufactured by the Terre Haute Car & Manufacturing Company, Terre Haute, Ind. The axles are $4\frac{1}{2}$ inches in diameter and the journal boxes are what is known as the W. W. type, or Westervelt anti-friction box. In this device a small paddle is attached to the end of the axle, which dips up the oil and passes it on to the journal.

The sand boxes are located in the vestibule and are of capacity for several bushels. The portion which carries the valve gear and which extends below the floor is surrounded by a waterproof case, which prevents the accumulation of moisture or mud about the valves that is thrown off by the wheel. The hose which leads the sand to the rail is cut diagonally at the lower end, the open end being forward. This also prevents an accumulation of mud and dirt, which might tend to choke the flow of sand.

It requires fourteen cars ordinarily to cover the two lines, with four additional on Saturdays and Sundays. On the Willoughby branch and at the terminals of the main line the cars are allowed to lay over after each trip for an hour to allow the motors to cool off. This, it is found, is a very essential practice on account of the high speeds. In case the cars were to run continuously without this lay-over they would make about 443 miles a day.

The trolley wheels are cast from a special mixture and have an unusually deep flange. The bushing is large, being $5\frac{1}{2} \times 2$ inches, and the wheels last generally about a week. Ordinary wheels would wear out in one day on account of the high speed. These, as well as the gears, which are of cast steel, are purchased from Horsburg & Scott, local manufacturers.

An electric locomotive which is equipped with four motors serves to handle the construction train and in winter serves as a snow plough, a nose and flange being attached.

From extensive tests to obtain the total power consumed by the car at different speeds it was found that the rise in power slightly exceeded the rise in speed. The maximum power obtained was 153 h. p. during a start when a high speed was quickly attained. Running at a speed of twenty to twenty-five miles per hour the power was from 30 to 40 h. p.; at speeds of thirty to forty miles per hour, from 80 to 100 h. p. were required, and from a dynamometer test to ascertain the power for hauling a trail car the drawbar pull was found to be from 500 to 650 pounds to give a steady acceleration at a speed of from 18 to 34 miles per hour. From the tests it was assumed that a drawbar pull of 500 pounds would be just sufficient to overcome the friction of the car, and for a car weighing twenty tons the total friction is estimated to be from 20 to 25 pounds per ton.

The number of passengers carried during 1897 was 526,098, and for the first seven months of 1898, 349,528. There is also a considerable income from express and freight traffic. The express business is under the management of one of the express companies, who furnish their own messengers. A large number of people who do business in Cleveland or Painesville reside on the line of the road and provide a steady patronage, while the pleasure riding is a marked feature of this system.

The officers of the company are C. W. Wason, who is president, and who is also connected with other lines, as noted above. Mr. Wason began his railway experience on one of the city lines ten years ago, having succeeded his father, who had been identified with the Cleveland railways for a long period. H. A. Everett is general manager; J. A. Beidler, vice-president; Mr. F. S. Borton, secretary, and L. E. Beilstone, superintendent. The city office of the company is in the Garfield Building.

The Boston Subway.

At a time when it has been officially announced that the entire Boston subway is practically completed and will shortly be thrown open to the public, it seems fitting to allude to some of the adverse criticism of some of the daily press, which have stated that the subway was not popular with the general public.

We think the best argument that we can offer is the picture which we print herewith, reduced from a photograph, showing the suburbanites of Boston heading for the Park street entrance of the subway at a little after 5 o'clock on a recent afternoon.

We also understand that the average number of people who

purchase tickets to enter the subway between the hours of 5 and 6 on any week-day evening is about 4,500 to 4,800. When we consider that this does not include those presenting eight-cent checks and those having passes who travel through the subway, we think the above a sufficient and unanswerable argument as to the popularity of this great undertaking.

ENTRANCE TO BOSTON SUBWAY.

As to its engineering features, we think it is conceded by all those competent to pass on its technical aspect that it is one of the best designed and constructed examples of modern engineering skill of its kind. Considering that only a small portion of it has been open and that for only twelve months, it has evidently demonstrated itself to be a success.

The Buffalo and Lockport Electric Railway.

BY O. E. DUNLAP.

THE cities of Buffalo and Lockport, N. Y., are now connected by an electric railway, the service on which is very similar to that afforded by the Buffalo & Niagara Falls Electric Railway Company between Buffalo and the Falls. The company owning the line between Buffalo and Lockport is known as the Buffalo & Lockport Railway Company, and the men interested in the company are prominent in the line running to the Falls. The presi-

TRANSFORMER ROOM, BUFFALO & LOCKPORT R. R.

dent of the road is Hon. W. Caryl Ely, who is also president of the Buffalo & Niagara Falls road. The general manager of the new line is Burt Van Horn, who occupies a similar position on the Buffalo-Falls road. The superintendent is C. K. Marshall, he being also superintendent of the other line mentioned. This makes plain that the interests of the two electric roads are mainly

identical and that in many ways they will contribute to the success of each other.

The cars of the Buffalo & Lockport Railway are at present operated over the tracks of the Buffalo & Niagara Falls road from North Tonawanda to Buffalo, but very recently the Buffalo, Kenmore & Tonawanda line has been purchased by one interested in the Buffalo & Lockport road, and it is the general expectation that in the very near future the Buffalo-Lockport cars will have an independent entrance into Buffalo over the tracks of the line so secured. From North Tonawanda to Lockport the cars are operated over the old branch of the Erie road, which has been leased and transformed from a steam to a trolley road, this being the first transformation of the kind in Western New York. For this reason it has attracted much attention.

The distance from Buffalo to Lockport over the route is about 25 miles, North Tonawanda being situated about midway between the two terminal cities. The rails used on the Erie line were 60-pound, and it was found necessary to relay about one mile of track two miles west of Lockport, and in this work 80-pound rails were used. The contract for the reconstruction of the Erie branch was awarded to J. G. White & Co., and Mr. John A. Wilson had charge of the work for them. From North Tonawanda to Lockport the line has a single track, with turnouts at Martinsville, Pendleton Centre and one a short distance west of Lockport. It was necessary to bond the track, and in this work two gangs were employed, one working days and the other at night. A three-inch horseshoe bond, with No. 0000 wire, was

CARS PASSING AT PENDLETON CENTRE, SHOWING TYPE OF STATION, B. & L. R. R.

used underneath the rail. About twenty days were consumed in this work.

In carrying out the contract Mr. Wilson used a construction train consisting of an engine, three flat cars and a caboose. The wire was strung with the train in motion, the wire being laid on the cross arms of the poles from the end of a boom on one of the cars. Each day about five miles of wire was run out and laid. The trolley wire is suspended from a double line of poles set 88 feet apart. On the poles on the north side of the track two 500,000 c. m. feeder cables are strung. On the south side of the right of way poles have been erected for a power transmission line from North Tonawanda to Lockport.

The poles of the transmission line are set 100 feet apart and three No. 0000 wires run along over the single cross-arm placed on them. The porcelain insulators used are the same as in service on the Buffalo-Niagara Falls power transmission line. The tops of all poles are 22 feet above the track. For about three-quarters of a mile in North Tonawanda the trolley wire is suspended on an arm support. Niagara power is being used to operate the road, the connection between the two transmission lines being made in North Tonawanda. The plan of the company is to feed the Lockport end from the transformer station in Lockport and the westerly end from a transformer station located in North Tonawanda.

Many advantages were secured by the Buffalo & Lockport Railway Company in their very clever move in leasing the old Erie branch from North Tonawanda to Lockport. It assured

them of a splendid right of way, a recognized route of travel, well-built suitable stations, a good freight and milk business, etc. In order to handle the freight business to which they have fallen heir, they have purchased two electric locomotives from the General Electric Company. Each of these locomotives weighs 45 tons and is equipped with four No. 55 motors. They have a guaranteed speed of 15 miles an hour and have pulled as many as 28 loaded cars over the line. A significant feature of these locomotives is that they are identical with the locomotives to be made by the General Electric Company for the underground railway service in London, England.

The Buffalo & Lockport Railway Company have 10 cars, two of which are combination baggage and passenger and eight combination smoker and passenger. The color of the cars is yellow, exactly like the cars of the Buffalo & Niagara Falls road. Each car is fitted with four No. 57 motors, with a rated capacity of 52 h. p., the total horse power to each car, therefore, being 208 h. p. The Brill Company, of Philadelphia, built the cars.

The speed over the line is quite a little faster than that made by cars on the Buffalo & Niagara Falls road, and the time consumed in running from Lockport to Buffalo is a little over an hour. It is the company's intention to give a half-hour service between the two points. Under the Erie management four passenger trains were run each way every day between Buffalo and Lockport, and it is apparent that the electric cars will afford a better service. There was one freight a day between North Tonawanda and Lockport, and this the electric locomotives can easily surpass if necessity requires. A valuable feature of the company's rights is that it controls the Lock City road, and, under a franchise granted by the Common Council of that city, it has the right to handle freight through that city over the tracks of the local road between the hours of 11 p. m. and 5 a. m. The lease of the Erie gives unlimited freight rights at all times. Lockport is a city where considerable manufacturing is done, and considerable of the freight to and from these establishments will pass over the Buffalo & Lockport Railway Company's tracks.

The company has constructed a brick car barn in the rear of the Lockport depot, where their cars will be kept. In this building the transformer room is located, as well as a convenient workshop. In the transformer room two 500 h. p. rotary converters, static transformers and the necessary switchboards have been installed by the General Electric Company. The switchboard has three panels and is of blue marble.

TEN MILES OF TRACK AS THE CROW FLIES, B. & L. R. R.

The possibilities of the cars making a rapid run over the line between North Tonawanda and Lockport is enhanced by the fact that for over 10 miles the track runs in a straight line, with not the slightest curve for that distance. The stations along the line from North Tonawanda east are Martinsville, three miles; Hoffman, four miles; Pendleton Centre, eight miles; Hodgeville, nine miles; Lockport, 13 miles. The road runs through a beautiful farming country, and the advent of the trolley is welcomed as the successor of the steam locomotive, because farmers recognize that there is less liability of their crops being destroyed by fires started by flying sparks from the locomotives. They also welcome a better passenger and freight service, and there is no doubt

but that the road will become a factor of some consideration in placing their fruit on the market.

One of the ideal features of the construction of this new electric railway is the fact that it provides a right of way for a power transmission line from North Tonawanda to Lockport, and thus it is likely, in more ways than one, to become a material aid in developing various interests in Niagara county. Lockport is not so rich in power resources but that it is very pleased to feel the thrill of the industrial advancement consequent upon the presence of the transmitted power of the big generators in the central station of the Niagara Falls Power Company.

45-TON ELECTRIC FREIGHT LOCOMOTIVE, B. & L. R. R.

For many years Lockport has longed for an electric line from that city to the shore of Lake Ontario at Olcott, and it is understood that the men back of the Buffalo & Lockport road will build this line at an early date, they seeing in it the prospects of good travel, not from Lockport alone, but from the larger centres of population, Buffalo and Niagara Falls. The country through which it would run is rich in fruit and general farm produce, and the freight traffic would be an important item, while it would also afford a better passenger service to a large section of country through which only one railroad runs at present. The company also have in contemplation the extension of their line down along the Erie Canal to Middleport, Medina, Albion and other places between Lockport and Rochester. In fact, the time may not be far distant when it will be possible to ride from the Queen City to the Flour City on cars driven at a high speed by Niagara power.

It may be mentioned incidentally that Hon. W. Caryl Ely, who has thus given his energy to the development of a second great electric railway, is vice-president of the American Street Railway Association. He is a gentleman who has been attracted to the electric railroad field by a full and proper conception of the wonderful possibilities of development the electric road brings to a locality through which it is run. He was the chief promoter of the Buffalo & Niagara Falls road, which has won pleasing success. Mr. Ely is not a temporary star in street railway circles. He is of the first magnitude, and, to use his own words, has "come to stay." In Burt Van Horn he has an able lieutenant, and it will be well worth watching the career of these two men in the electric railroad development.

Electrical Propulsion on Country Roads.

BY JAMES ASHER.

IN the application of electricity to wagons on country roads, it has hitherto been considered necessary to have a battery on the wagon to supply electricity to the electric motor. Little use has been made of batteries in this regard because of their inconvenience, weight and cost of maintenance.

I will now propose a method of using electric motors on common roads. Two parallel overhead wires may be supported either by cross-arms on posts or by wires stretched across the road overhead. There may be two trolley poles extending up from the wagon to the wires. Each trolley pole supports at the top a heavy bare conductor bent into an approximately elliptical form, which may be several feet long, which is pressed up-

wardly against the line wire and is transverse thereto. It will now be understood that the electric current enters the elliptical wire at the head of one trolley pole, descends along a conductor on this pole, traverses the electric motor, which is mounted under the wagon, then ascends the conductor on the second trolley pole and traverses the elliptical rubbing conductor at the head of this pole, and finally enters the second overhead wire. The elliptical conductor at the head of each pole would be similar to that of Siemens, which is used on European electric railways. The trouble arising from the jumping off the trolley wire by the trolley is avoided by means of the rubbing conductor. This method of leading the current of electricity to and from the electric motor allows considerable lateral deviation on the part of the electric motor wagon and makes a simple overhead construction feasible at corners.

Such a line of poles and wires could be constructed without great expense, and the motor wagon would not be much heavier than an ordinary wagon; the only additional weight would be that of the small electric motor and its accessories.

A motor wagon, actuated by a current of electricity arriving by one of the overhead wires and returning by the other, could draw several loaded trailers. In some cases it would be advisable to have a heavy motor wagon built expressly for drawing trains of loaded wagons or carriages. In this manner some of the advantages of an electric railway might be secured without incurring the great expense of a line of ties and rails. Much steeper grades could be ascended than is the case with electric railways. Only the motor wagon would require a steering mechanism. Means of reversing the motion of the traction or motor wagon would be provided in most cases. The wagons in the train should be furnished with brakes. Perhaps as many as ten heavily loaded wagons could be drawn by one motor wagon of about 12 h. p. By means of this system several neighbors might frequently unite to form a train of wagons loaded with grain or other produce for market even thirty miles away. Only one person would be required for the management of the whole train.

This system of electric traction would possess not only the cheapness of the telpherage system, but also the ability to draw loads which the telpherage system could not move. In the winter season, when the ground is covered with snow, the motor wagon could draw enormous loads of produce or of passengers on a train of sleighs. Thus, on common roads, much of the work that is commonly performed by horses could be electrically performed with facility, speed and small expense.

Power Consumption in Electric Railroading.—III.

BY S. T. DODD.
ACCELERATION.

The next question which demands our attention is the power expended in acceleration. How many pounds of pull does it take to give a certain weight a certain velocity in a fixed time? What accelerations are usually attained in practice? and what are the attainable and limiting rates of acceleration?

The answer to the first of these questions is mathematical rather than experimental. If a force P acts upon a weight W to produce acceleration, leaving out of account for the present the force necessary to overcome friction, the acceleration F will be equal to $32.2 \times P/W$. Forces and weights being expressed in pounds and acceleration in feet per second per second, it will be more convenient in what follows to express acceleration in terms of the gain in one second of velocity measured in miles per hour, which we will write F_m . $F = F_m \frac{5280}{3600}$. Transforming

the equation above we get $P = \frac{FW}{32.2}$. Substituting for F ,

$P = F_m W \frac{5280}{3600 \times 32.2}$ or $P = F_m \times W / 21.9$, and if $W = 2,000$ pounds we get the force per ton equal to the acceleration multiplied by 91.5, or pounds per ton = $F_m \cdot 91.5$

The curves in Fig. 3 show the accelerations which are obtained in actual practice. Curve No. 1 shows a start of an 11-car train on the Chicago, Burlington & Quincy R. R., copied from data given by Mr. Wm. Forsyth in an article "Tests of Locomotives in Express Service," published in the "National Car and Locomotive Builder," April, 1893.

Curve No. 2 shows the start of a Manhattan Elevated train, taken from an article by Mr. George L. Fowler in the "Railroad Gazette," March, 1897. Curve No. 3 shows the start of an

Akron, Bedford & Cleveland electric car. Curve No. 4 is a corresponding observation made on the Cleveland, Painesville & Eastern Road. Curve No. 5 is taken from an article by Mr. W. B. Potter, engineer of the railway department of the General Electric Co., and shows the starting curve of a car equipped by that company with a view to experimenting upon very high accelerations.

The table opposite shows the number of pounds per ton used for acceleration in the various starts shown in these curves, calculated from the acceleration by the formula derived above.

The limit of possible acceleration in railroad work is naturally fixed by the slipping of the driving wheels. It can be shown that the start represented in Curve No. 5 is very near to this limit. It is generally acknowledged that the adhesion of wheels to rails is, under good conditions, one-fourth of the weight upon them, and under ordinary conditions, one-fifth. If we assume, however, one-fourth, and assume moreover that the whole weight of the car rests upon the driving wheels, it will be seen that the limiting accelerating force is about 500 pounds per ton, and allowing 30 pounds per ton for frictional resistance, we have about 470 pounds as the limiting acceleration. Curve No. 6 shows this limit. That such starts as this are not uncomfortable, if made smoothly, is testified to by the fact that we experience negative accelerations of comparable amounts upon our interurban cars without feeling any discomfort. I have myself noted a stop from 25 miles an hour within 90 feet, and from

FIG. 3.

41 miles per hour I have seen a stop made in eight seconds. As these represent a negative acceleration of 475 pounds per ton it is evident that the rails were in pretty good condition and that we had an adhesion of about one-fourth. I might note that both these were emergency stops and a little more sudden than ordinary, but I am told by motormen upon our suburban roads that, with brakes in good condition, they can always make a stop from 50 miles an hour in 5 poles, or 450 feet, which represents a negative acceleration of 365 pounds per ton. From these facts I think we can conclude that the limit of possible acceleration is only fixed by the adhesion of the wheels to the rail, or by the willingness of railway managers to expend extra power for the sake of increased schedule speeds.

GRADE RESISTANCE.

It is often stated as an advantage of electric traction that an electric car is able to mount steeper grades than a steam driven train. This statement, while true, is often misstated, or rather misunderstood by those who make it. The advantage does not lie, as many seem to think, in the electric current per se, and when steam railroad managers think it advisable to equip an 800-ton train with 8,000 horse power in motive power, the difference will not be as apparent as it is to-day. The force necessary to lift a train up a grade is the same fraction of the weight of the train that the rise of the grade is of horizontal length. As an example of some of the grades we meet in practice, we may note that the Cleveland City Railway is operating on Woodland avenue a grade of 9 per cent., and pulling trailers on that. The Cleveland Electric Railway is operating on Seneca street hill a

¹Paper read before the Civil Engineers' Club, Cleveland, O.

grade of about 11 per cent.; the Akron, Bedford and Cleveland Railway is operating on North Hill, Akron, a grade of 13.5 per cent. To compare these resistances with those ordinarily experienced in acceleration, the latter part of the table below shows the number of pounds traction per ton of train necessary to mount such grades. An inspection of the table shows that the tractive effort necessary on ordinary grades is comparable with that necessary for such acceleration as we ordinarily meet in electric railroad practice.

POWER CONSUMPTION.

Let us apply the data of the foregoing discussion to some problems in order to determine the power expended in particular cases. Let us take as a first illustration an ordinary city car. These cars, together with the equipments, will weigh about 12 tons. As may be noted any night after 12 o'clock going out either Prospect street or Detroit street, the maximum speed which such equipments will attain on a level after the period of acceleration is past, is about 20 miles per hour. Applying our formula for train resistance, $18 + .2V$, the frictional resistance of such a car at this speed is about 22 pounds per ton, giving us a horizontal effort of 264 pounds necessary to propel a 12-ton car. 264 pounds at 20 miles per hour is equal to 14 horse power. Assuming that the efficiency of such motors as are ordinarily used at this speed is about 75 per cent., this gives an input at the trolley of 18.8 horse power or 14 kilowatts, which, at 500 volts is equivalent to 28 amperes. This represents approximately the amount of current necessary to propel such a car.

As a second illustration let us take as an example an ordinary double truck inter-urban car. The weight of the car body and truck empty is about 15 tons. The motors ordinarily used for

tons. You will note in riding on the cars that a speed of 35 to 45 miles an hour is common, and that after you have gone a mile or so from a stop you attain a speed of 50 miles per hour.

What current do the motors take to propel the car at this speed?

The train resistance on a level is $(18 + .2V)W$; since in the present case W is 22 tons and V is 50 miles, we have 616 pounds effort necessary for propulsion. 616 pounds at 50 miles per hour is 8.2 horse power, which represents the output of the motors at full speed. For motors of this size we may estimate the efficiency at about 82 per cent. This means 100 horse power input to the motors.

As for voltage, a visit to the power house will show that they carry a pretty high voltage (about 600) and heavy feeders, so we can estimate they get 550 volts at the motor terminals; 100 horse power at 550 volts is 135 amperes. My estimate based on the data I have given you is that it takes about 135 amperes to propel these cars after they have attained full speed.

Another interesting question is—How much current does it take to start these cars? If we are allowed to make some assumption we can estimate somewhat near. These cars seem to me to accelerate at the start a little slower than our ordinary suburban cars. Let us suppose they start with an acceleration of 150 pounds per ton. 150 pounds per ton is a total effort of 3,300 pounds. To this must be added about 23 pounds per ton for frictional resistance, making a total of 3,800 pounds.

How much current flowing through these motors will produce a horizontal effort of 950 pounds per motor? To determine that, it will be necessary to know the speed of which the motors are capable at some definite voltage at this torque. We may note from the car windows that a speed of 35 or 40 miles is very soon attained, but it is not until after we have traveled a mile or so that we reach a speed of 50 miles per hour. We will not be far from correct if we figure that the car maintains an acceleration of 150 pounds per ton up to about 25 miles per hour, and then as the controller is entirely cut out the motors continue to speed up and current falls off together with the acceleration. An effort of 3,800 pounds at 25 miles per hour is about 25.4 horse power. Assuming again the efficiency of the motors at 80 per cent. we get an input of 317 horse power, or 236 kilowatts. At 550 volts this indicates a current of 430 amperes as the probable current during the period of acceleration.

In conclusion, let me repeat again the statement I made in the beginning. It often seems that the equipment of a single car with one or two hundred horse power in motive power is an unnecessary waste of power, but when we come to consider the weight of car and loads we are operating—the rapidity with which we are compelled to accelerate these weights on account of our frequent stops and the grades which our ordinary highways compel us to climb, we see that ordinary mechanical principles justify the demands of practice for heavy equipments.

HORIZONTAL EFFORT FOR VARIOUS ACCELERATIONS AND GRADES.

ROADS.	A	G	H E. PER TON.
C. B. & Q. STEAM	1		36.5
MANHATTAN ELEV. STEAM	2		55
A. B. & C. ELECTRIC	3		183
C. P. & E.	4		238
SPECIAL G. E.	5		348
LIMIT			470
WOODLAND AVE.		9%	180
SENECA ST.		11%	220
NORTH HILL		13½%	270

such equipment weigh about 3,000 pounds. We can estimate the total weight, including two motor equipment, and a few passengers, at about 20 tons. You may note that these cars run upon a level at a speed of about 28 miles per hour. Applying our formula we get 23.4 pounds per ton, or a total of 472 pounds horizontal effort necessary for propulsion. At 28 miles an hour this is equivalent to 35 horse power. Figuring the efficiency of these larger size motors at 82 per cent., this gives us 43 horse power, or 32 kilowatt input, which, at 500 volts, gives 64 amperes, or 32 amperes per motor as the ordinary running current.

Another interesting question is—What should the starting current amount to in cars of this weight? If we take the curves of acceleration which are plotted upon the sheet for the A. B. & C. car, you will see that at the maximum as the acceleration begins to fall off, which corresponds to the point where the controller is entirely cut out, we have an acceleration amounting to 1.25 miles per hour per second. This is equivalent to 114.5 pounds per ton, or for a 20-ton car about 2,300 pounds horizontal effort necessary at this point. As the speed attained with this pull is approximately 18 miles per hour, then the motors are delivering about 110 horse power; figuring the efficiency of the motors at 80 per cent., we get a total input of 138 horse power or 103 kilowatts, which at 500 volts, represents 206 amperes as the starting current.

Let us consider as a final example the cars of our latest inter-urban road, the Lorain and Cleveland Railroad. No tests have as yet been published on this, but we are promised by the engineers a complete set of tests as soon as the road is in running shape, and when such tests are published we will have some basis for judging the reliability of these figures. Such cars will weigh empty about 15 tons, or 30,000 pounds. They are equipped with four motors, and while I am not acquainted with the data of these motors, they must weigh in the neighborhood of 3,000 pounds each. We can safely estimate the weight of car equipment as 22

The Canon City-Cripple Creek Power Transmission Plant in Operation—Mines Run by Electricity.

AT noon on August 17 Governor Alva Adams pressed the button which was the means of putting in motion the massive machinery of the Colorado Electric Power Company, at Cañon City, Col. The electric current was transmitted to motors at the Cripple Creek gold mines, twenty-four miles distant, where arrangements have been carried out to have electricity take the place of the usual steam power equipment that has heretofore been in use. This means the successful accomplishment of another big undertaking which adds to Cripple Creek's claim as the foremost gold producing camp in the United States, and at the same time records another instance where electricity was considered as the power par excellence for mining purposes by a community of practical men.

In brief, the scheme is to generate electricity at Cañon City, which is in the midst of extensive coal fields, and transmit the

power to Cripple Creek, where coal sells at a high figure. This will enable mines to be operated at a profit that have heretofore been close to losing propositions, and at the same time effect a very great saving in running expenses with the large producers. This promises to be a very important point in the future development of the camp.

The plant is one of the largest and best equipped electric power concerns in the West. The equipment consists of three Hamilton-Corliss engines, with a combined capacity of 9,000 h. p. direct connected to three Westinghouse three-phase generators of 2,100 kilowatts capacity, wound for 500 volts, making three separate generating units, one of which will always be kept as a reserve in case of emergency. For exciting the fields of the main dynamos there are two "Kodak" exciter outfits, each of which is capable of exciting all three of the main dynamos.

The engines are supplied from a battery of Heine safety tube boilers, and the exhaust steam is taken care of in a surface condenser. The air and circulating pumps and feed pumps are all of the "Snow" make.

There have been installed at the main station four transformers that step up from 500 to 20,000 volts, at which pressure the current is delivered to the transmission line. The first sub-station is near Victor, on the saddle between Battle Mountain and Bull Hill. The location of the second sub-station is on the saddle between Gold Hill and Globe Hill, near Cripple Creek. At each of the sub-stations the current steps down by means of transformers to 500 volts, at which pressure it is delivered to the motors in the mines. In addition, lights are to be supplied from the same wires used to furnish power.

The construction of the transmission line is most substantial; particular pains have been taken in protecting it from lightning troubles. In addition to the lightning arresters in the generating station at Cañon City and in the sub-stations lightning arresters have been installed at a number of points along the transmission line, the "Wurts" arrester being adopted throughout the installation.

It should be mentioned that in addition to the twenty-four miles of line between Cañon City and Cripple Creek there is about six miles of line over the camp, which will make the total length of the system about thirty miles. The work of constructing this system was commenced last September, and after nearly twelve months everything is in readiness. The entire line is patrolled by experienced linemen; they carry with them a telephone specially adapted for their work, which they connect with the main line at any point, and send in word wherever they find a break. Western Union call boxes are stationed along the line, and through them the patrolman must report where he is every hour.

The main station of the Colorado Electric Power plant is a substantial structure, 140x106 feet, constructed of brick, stone and cement, with steel trusses and corrugated iron roofing, and allowance has been made so that the entire plant can be duplicated without the addition of another smokestack or extra condensers.

This plant has cost probably not less than \$750,000. The company has among its stockholders Mr. John D. Rockefeller, Mr. Andrew Carnegie, and others of like prominence.

The transmission line was erected under the supervision of the Mountain Electric Company, in Denver, for which they used a specially designed insulator, gotten up by them. This company by careful and painstaking work has gained a reputation as being second to none in this section for transmission construction work. The generating apparatus was installed by the Westinghouse Company and the steam equipment was put in under the supervision of the Stearns-Rogers Company, in Denver.

It has been carefully computed that there will be a saving of 25 per cent. in the operating expenses of the mines if electricity is used, in so far as the matter of hoisting the ore, running drills and doing whatever steam can do is concerned. Then, again, there can be no question as to the superior convenience.

Water Power Plants in the South.

THE Columbus Power Company, of Columbus, Ga., has recently let a contract for the construction of a stone dam and power house for the purpose of developing 8,000 electrical horse power. The head under which the wheels work is 40 feet, and the contract for these wheels has been let to the Holyoke Machine Co., Worcester, Mass. One pair of 39-inch

wheels will be used to drive a 900 kilowatt generator at a speed of about 200 revolutions. Separate wheels will be used to drive two exciters. Each exciter will be large enough to excite all of the generators. The company proposes to install only about three generators at first and will prepare their power house so that additional wheels and generators can be added as the company's business will warrant.

Mr. Wm. C. Whitner, who has recently been acting as Southern agent for the Stanley Electric Mfg. Co., of Pittsfield, Mass., has resigned this position to accept that of chief engineer of the Columbus Power Co., and in the future will devote his attention entirely to the engineering of power transmission work.

Another plant in which Mr. Whitner is interested is that which is about to be built by the Spartan Power Co., of Spartanburg, S. C. This company will develop water power ten miles distant from the city of Spartanburg, on the Pacoiet River, transmitting about 1,000 horse power to the city at a high voltage; probably 12,000 volts will be used. A sub-station will be built within the city limits, and step-down converters will be used to reduce the voltage to 2,000. It is estimated that all of this 1,000 horse power will be required to light the streets and to furnish lights and power to the citizens. The details of the plant have not been worked out beyond the fact that a stone dam and power house will be built, and two 400 kilowatt multiphase alternators will be direct connected to horizontal wheels. It is proposed to use enclosed alternating arc lamps of 2,000 c. p. each.

Testing Arc Light Circuits.—I.

BY W. H. MARKLAND.

A SUBJECT that has not received the attention it deserves by electrical writers and by a very large number of managers of central and isolated plants operating series arc lamps is that of testing circuits for grounds, escapes and e. m. f. of circuits while current is on. My observation is that about nine-tenths of the arc light stations rely wholly on the magneto call bell for all testing. Why this should be in these days when reliable high reading voltmeters can be had at reasonable prices is hard to understand by one who has had the use of the above. Every station manager should, and no doubt does, wish to know the state of the various circuits while current is on. Both in respect to leaks or grounds and the e. m. f. required for lamps. We all know that grounds come on and go off, also that escapes occur under the high e. m. f. of the dynamo that will not show up by magneto test. These grounds are often troublesome and hard to locate by magneto, but with the voltmeter the grounds cannot only be detected, but their nature, either "dead" or escape, told and their location ascertained with great accuracy, all this being done in the station by superintendent or engineer in "just no time."

The following is an illustration of actual practice in the writer's experience: A ground showed up in testing with a voltmeter that could not be detected by the magneto. Test showed it to be located between the first and second lamp on negative side of circuit of 45 lamps. Trouble men found the line wire down on guy wire to telephone pole in location indicated; the covering of wire had not cut through and weather was dry, thus no damage resulted. Had this not been detected noisy telephones and possibly burn-outs would have resulted later on.

In another case an escape was detected by voltmeter on circuit of 24 lamps, 10 lamps out from positive side. Trouble men found a wire down on iron work in location indicated, in building over shavings where, if the insulation of the wire had begun to burn, it might have caused a fire. The above are only two of many cases where escapes that the magneto would not show up have been located by a voltmeter. The voltmeter is particularly valuable in locating slight grounds during seasons of dry weather in order that the lines may be in good order and clear for the rainy season, which, we all know, causes the superintendent no end of trouble and fireworks on account of all the weak points in the insulation breaking down at one time. With large dynamos, such as 125-lighters, it is especially valuable to know all the weak

spots of lines. In case of a dead ground the same can be located with great accuracy. The time saved by being able to send trouble men to the exact spot where the ground is will more than pay interest on cost of voltmeter.

Another good use of the voltmeter is in the event of arc circuits being crossed with other wires to tell what class of wires they are, either low tension, direct current, alternating current, arc, or trolley wires. The writer has been able to tell by a voltmeter when an arc circuit was crossed in one case with a 110-volt circuit, another with 500-volt trolley and one with a telegraph circuit. As it was known where the arc circuits were close to wires of the nature indicated, there was no difficulty in going to almost the exact spot.

Another good use of the voltmeter is to test the e. m. f. of a circuit of lamps. In this way the average e. m. f. of each lamp may be figured out, and if too high or low the lamps adjusted to the proper length of arc. The writer had one case where he was helping out a friend. By taking the total e. m. f. of a circuit when the current was on, and after deducting for line wire and dividing by the number of lamps, it was found that each lamp was taking 55 volts, or 7 volts more than necessary per lamp, or for the 60 lamps, 420 volts, or nearly enough more than necessary to run nine additional lamps with lamps properly adjusted. I have not mentioned current, it being assumed on series arc circuits that it was normal at about 9.6 amperes. In this case the lamps were afterwards adjusted lower and more of them put on the dynamo. The superintendent of the station was a first-class man, but his directors could not see the use of these new-fangled affairs. Possibly now, when they find that more lamps can be run from the same dynamo and coal pile, they may think differently.

Another good use of the voltmeter is in testing the dynamo, especially after making repairs. Without the voltmeter we simply load up the dynamo with the number of lamps it is supposed to run and let her go. The lamps may take anywhere from 40 to 60 volts, and it is not known whether the dynamo is doing its proper work or not. But with the voltmeter the exact e. m. f. the dynamo is generating can be read off and the dynamo be loaded up until it is generating its full e. m. f., even with more or less than its correct number of lamps. The writer generally tests dynamos after repairs with the greatest number of lamps they will carry, or up to the point of flashing or the current falling, and by reading the e. m. f. it is known how many lamps can be put on the dynamo in the future. This is a case where both the dynamo and lamps are tested to see that each is right. For detecting slight or bad grounds to frame of dynamo the voltmeter comes in very handy. On one occasion a cross in the dynamo field was reported to me by a man of no mean ability. The magneto would not tell the story. The voltmeter located the trouble in the armature. As we had an extra armature and no extra field, we thought the voltmeter half paid for itself on that one occasion. Now, some may say that all this is very nice, but it costs money to get voltmeters and multipliers, and that the superintendent has plenty to do without all this in looking after the coal supply, to pacify a customer who wants lower rate, to see that Smith's light is as good as Jones' and to be generally courteous to customers and properly explain that electricity is in its infancy, and a thousand and one things that go to while away the weary hours of the superintendent so he may object to any more work. But when we consider that one can figure out the e. m. f. taken by lamps and resistance of grounds by tests made every evening and morning of 10 loops and record the same without hurry in 10 minutes, it can be seen that the superintendent can do the same and yet have a few minutes during the day to talk to carbon agents.

Some articles have been written about testing arc circuits by means of a galvanometer. While the writer is thoroughly familiar with the galvanometer and bridge, he has never been able to get any results on an arc circuit that were worth a cent, and came to the conclusion long ago that the galvanometer should remain with telegraph lines, where it originated.

THE ALBION POWER COMPANY, which from an electric plant situated at Waterport on the Oak Orchard Creek, is to supply Albion, N. Y., with lights and power, has recently been organized with a capital of \$50,000. They will in the near future put up a brick power house with an iron roof and install an 80 light Brush machine and two 1,500 light alternators. The line, consisting of No. 6 wire, will be 40 miles in length.

Positive and Negative Economies in the Operation of Small Electric Light Plants.¹—I.

BY E. P. ROBERTS.

IT is generally considered quite sufficient to keep an account of expenditures and receipts, and to ascertain the amount of the balance at the end of certain periods, and if there is a balance, it is sufficient cause for jubilation.

Upon examination of a great many plants, I feel sure that a great many of them, probably the majority, could reduce their operating expenses from 10 per cent. to 20 per cent. if—First—they were better informed as to the conditions under which they were operating, and, Second—knew how to improve the conditions. It should also be noted that at the same time that reduction of expenses would be obtained, a better service would be given, with attendant better feeling on the part of the consumer, both public and private.

If we take up the consideration of the plant from the standpoint of a general superintendent, and desire to investigate its condition, we must first ascertain the useful results and the losses in each step, and then we can discuss changes either in the plant or in the handling of it, what such changes would cost, and the advantages resulting therefrom, and whether any or all shall be taken up.

We may start as follows:

- 1st. The production of power at the dynamo pulley.
- 2d. The conversion of mechanical into electrical energy.
- 3d. The delivery of the electric energy to the various points where it is to be converted into light, heat or power.
- 4th. Its conversion as above stated.

Taking the above in order, we have first to consider the production of the driving power. In this case we will work backwards, that is, from the dynamo to the coal pile. If the plant is not direct connected, we will have belts and probably shafts. Are the belts tighter than advisable? If so, it may be because they are oily and dirty; this means increased depreciation as well as increased power. Evidently they should be cleaned. Possibly the belt centres are too close together, and this distance cannot be increased. Possibly larger pulleys can be placed, preferably (if not making belt speed excessive) larger in diameter, but if this is not feasible, wider in face. Will this pay? Suppose a belt transmitting 100 h. p. costs \$100, and is running too tight and adds 3 per cent. (3 h. p.) to the friction more than it would do if running loose. Suppose to change to larger pulleys costs \$75 and the extra belt costs \$25 additional, making a total of \$100. Probably the life of the belt will be increased 50 per cent., say nine years, as against six. We then have for twelve hours run for 365 days and 3 h. p. a total of 13,140 h. p. hours. If the additional coal is 4 pounds per h. p., and coal costs \$1.50, we will have a saving of \$39.42 annually, and a lessened depreciation of \$5.55, or a total of \$44.97. Not only a saving of 45 per cent. on the investment, but also less probability of breakage of belt, of poor lights, because of slip, of hot boxes and consequent cost of renewals, and less oil (though same is not figured), and most important, less probability of shut downs. The above is only a small item, but how many managers would spend \$100 to save a belt slipping? The station superintendent must get along with resin.

Possibly the only remedy applicable is a tightener, not a very desirable method, but generally 99 per cent. more objectionable, wasteful and noisy than necessary because installed in the cheapest way possible. In such a paper as this we can not consider appliances in detail, so will pass on to the shaft. Here we find very little friction if the shaft is sufficiently stiff and in line, but if not, the friction may be from 15 per cent. to 20 per cent. of the rated load, and in many cases it is probably 10 per cent. more than necessary; therefore, for every horse power it transmits, it unnecessarily wastes in friction (if at the same rate as in previous example) \$13.16 annually in fuel, a considerable amount in oil, and increases the liability of hot boxes. The remedy may be a new and larger shaft, or new and better boxes, or the present shaft may only need alignment. The trouble and its amount must first be ascertained and then the remedy applied. Suppose that the shaft transmits 200 h. p. and loses only 5 per cent. more in friction than it should, how much can we afford to spend to save that 5 per cent.? The direct saving would be \$131.30 annually, which would be 10 per cent. on \$1,313.00, and this is the amount we could not afford not to spend, and without considering the incidental advantages.

Vol. XXVI. NEW YORK, SEPTEMBER 8, 1898. No. 540.

The Electric Railway Outlook.

THE meeting of the American Street Railway Convention at Boston this week will bring together perhaps a larger number of members and interested parties than has yet been recorded in the history of that eminently successful and useful organization, and we believe it is not the hope of having "a good time" that will draw many members hundreds of miles from their homes. Certain it is that the Association's proceedings are evidence of the great value of their meetings, many of the papers read at them being the only source of published information on some of the most important questions with which the electric railway official and engineer have to deal. What the technical progress of the year has to show will be very much in evidence at the exhibition of electric railway appliances held in connection with the convention. The ever present manufacturer's representative will need no assistance in setting forth that progress, and we are willing to leave it to him. But other topics besides apparatus will find the convention in a receptive mood. We could, for example, suggest a continuance of some previous discussions on the matter of freight business of electric roads. This is a field which, of course, many roads are debarred from doing by their charters, but most of the newer roads are so empowered but seem to have given the matter little more than passing thought. That an electric road is able to do a freight business at a lower rate than it can be done by the time honored horse and dray, goes without saying. This applies not only to the transportation of small packages, but seems to us particularly applicable to the handling of freight in bulk and of such weight as calls for special facilities. There is no good reason why in every manufacturing centre the electric railway company should not run a switch track into every factory and do the carting, so to speak, from the factory door to the steam railroad freight shed. In fact such a trolley carting scheme has only recently been evolved by the Chicago General Electric Co., who have issued a circular to the owners of factories contiguous to their lines of road, asking for their business. The response has been most gratifying and it is more than likely that the company will soon have a trolley cartage business in full swing. When it is considered that an electric freight car can be built that can easily take a 35 ft. curve, it will be seen how easy the problem is of getting to the door and beside the outgoing delivery platform of most factories.

The above refers, of course, more particularly to urban electric railroads, but applies in a still greater degree to suburban and interurban roads. Already these classes of roads are beginning to make themselves felt as a factor in the country's transportation facilities, and to just what expansion such roads are capable is admirably illustrated in the description, begun in this issue, of the five electric roads centering in, or rather radiating from,

Cleveland, O. During the past year these roads have carried considerably over a million passengers and have opened up a business which formerly did not exist at all. It is the old story of creating a demand by supplying the desired commodity. The experience had with these roads centering in Cleveland will no doubt be a guide to many others of a like nature, and those contemplating the building of similar roads will therefore find in Mr. Fairchild's description much to guide them in their equipment and operation. Here also, it will be noted, that a freight business will in time constitute no inconsiderable factor of the net income, and, if we are not mistaken, considerable of that business will be done in the shape of the haulage of loaded farm wagons, which will be taken bodily from the farm to the centre of the city. In anticipation of this class of traffic we need only recall that a rail truck is now being regularly manufactured, designed for the specific purpose of hauling farm wagons, and described in these columns recently.

There are still some problems in electric railroading on which the last word has by no means been said, and which relate to the nature of the source of power for hauling the car. Thus far the direct current has had undisputed sway on the car itself, and where the alternating current has been employed it has been merely in the form of a transmitter. Yet from time to time we hear of experiments looking to the application of alternating motors directly on the car. We believe that many electric railways would give a good deal to avoid the use of their heavy overhead feeders, and would welcome a system that would permit of using high tension feeding lines, with low tension local distribution. It is true that this can be accomplished by means of rotary transformers, and in fact this is the plan which will be adopted when the gigantic railway power stations now in course of construction in New York City are completed. But the rotary evidently introduces another transformation, which would be avoided by the employment of an alternating motor on the car; hence, while it appears that the problem is not a pressing one, in view of the present state of the art, every effort towards increased economy is to be encouraged. For that reason if for no other the efforts to apply the alternating motor direct to the car are to be commended.

The question of the storage battery in connection with electric railways is also bound to assume increased importance in the future. The installation of a number of large storage battery plants in the power houses and at outlying feeder ends of several prominent railways in the past is an indication that the utility of these storers and regulators of electric power is being gradually recognized, but thus far but a single road has been bold enough to operate with storage batteries on the cars themselves. The reports from this road are distinctly encouraging, and we are not at all so sure but that in time other roads may be similarly equipped where the conditions are favorable to that type of road. In contemplating the probable future of storage battery railroading we must not lose sight of the fact that it may be considerably influenced by the collateral progress in electrical vehicles; that type of conveyance must, and will, in time, evolve a distinct type of storage battery, and also methods of handling batteries that will unquestionably have a direct influence on the battery designed for the storage battery car.

For those who still object to the trolley paraphernalia within cities, the work accomplished during the last year in New York city must be cheering, indeed, and it is scarcely to be doubted that the underground conduit railway lines in New York city will have a marked influence on the future of electric railway work in the United States. This work, accomplished so thoroughly in such a remarkably short time, will be the pattern for much similar work in other cities. During the past year, also, every elevated railroad system in the United States, with the exception of one, has adopted electricity as its motive power, not only for reasons of convenience to its passengers, but owing to the still stronger demands of economy in operation. The only road which has not thus far adopted electricity is gradually losing its traffic, and will probably continue to do so until it adopts the new motive power.

We have touched on but a few of the topics which the members of the Street Railway Convention will probably find time to discuss at the Boston convention. The future of the electric railway was never brighter than it is to-day, and with the growing knowledge of the best methods of conducting the business, together with the experience in handling existing apparatus, and the improvements which are bound to be made as time

passes, it would appear that no better or remunerative field of operation for the employment of capital can be found than in this method of transportation.

The Trolley and the Fan as Health Givers.

THE great mass of citizens are wont to look upon trolley lines as mere transporters of human freight, and the current as well as the trolley as things to be avoided, if possible. And this, regardless of the great strides made within recent years in electro-therapeutics and the invaluable benefits its promoters have conferred upon mankind. Who would underestimate the value of electro-dentistry or doubt for a moment the usefulness, nay, the indispensability of the Röntgen rays? Besides, the electric current is employed for the production of a large number of medicinal agents and the health of entire communities is insured by the disinfection of sewage by means of electricity. We might, continuing in this strain, mention in detail the healthful influence of the electric light and the various application of electricity for heating and power purposes.

Needless as it may appear to cite examples in support of the above, it may nevertheless be of interest to select from the panorama of our daily life those bright spots which reflect credit on the fresh-air work done by the electric fan and the "deadly" trolley.

Thus we might mention the case of a man prominently identified with the banking and street railroad business of Brooklyn, who had heard of the illness of a woman and her little one, and that there was little hope for the recovery of the mother. Instead of sending boxes of dainties, he had a wire run from the railway circuit near the house to the sick chamber and an electric fan placed at the foot of the invalid's bed. His fresh-air scheme reduced the patient's temperature in a short time and the physicians are of the opinion that it has much to do with the patient's improved condition.

As an antidote to the much abused trolley car we are gratified to see the following novel and beneficent uses made of it in various parts of the country. From Pittsburg comes the report of the growing use of trolley lines for fresh air outings. Listen to these words of a business man who says he has barely enough time to eat each day and is enthusiastic in his eulogy of the new condensed vacation trips: "I have been riding around since 8 o'clock this morning, and although I am feeling pretty tired now, it's a healthier feeling of tiredness than I leave the office with every day. I have been out in the open country in every direction from Pittsburg, and it has only cost me about \$1.40. Besides I have breathed lots of fresh air, in an open car, and have seen bits of the country that surprised me. I am going to take these trips every time I get a few spare hours. People don't know how much good a series of trolley rides can do, if their time is limited, and they want the benefits of an outing."

A young physician, in a recent conversation, made the assertion that the number of children who actually owe their lives to the electric cars may be estimated by thousands. In support of this we quote his own words: "You can hardly calculate," said he, "the good that a ride into the country does a baby which is fairly prostrated with heat. It is possible to find along the lines of the electric railways places where the temperature is 20 degrees lower than in town. The cool, fresh breeze after a stifling hot day, in a close room in town, means a new lease of life for a child. I wonder that some fresh air society doesn't charter a car on some of the lines and reserve it in the evenings for mothers with sickly little children, letting them ride free. I don't know of any charity that would be cheaper and I don't know of any that would do more good here in Washington, where a five cent ticket puts within reach of everybody a luxury our grandfathers couldn't have had for a million dollars."

As to the extent to which this desire to get fresh air is carried it is encouraging to note the quick perception of our Philadelphia friends in the down-town districts who, instead of sleeping in their overheated homes at night or on the blistering brick pavements, are now spending their nights in an atmosphere more beneficial to their health. They now leave their homes at about ten o'clock at night, board a trolley car and in about an hour they have reached a spot in the Fox Chase woods where there is a difference of temperature of about ten degrees. Women and children go as well as men, and it is a novel sight to see hundreds of them camped about in the woods like so many traveling bands of gypsies. Their only baggage, however, is a pillow and a covering of some kind. Fox Chase is

free from mosquitoes and other insects which generally make outdoor life uncomfortable in summer. After sleeping or resting in the woods for several hours they return to the city and engage in their day's labor.

The term "deadly" as applied to the trolley must soon be altered to "health giving" among the populace.

Dr. John Hopkinson, D. Sc., F. R. S.

THE brief announcement of Dr. John Hopkinson's death while attempting to ascend one of the Alps, must have come as a severe shock to the entire engineering world, but more particularly to the electrical engineer in every land. For by the death of Dr. Hopkinson one of the most prominent and earliest workers in the electrical field has been removed from the scene of activity and a life resplendent with useful work and valuable contributions to science has been closed.

Dr. Hopkinson was born at Manchester in 1849, and was therefore only 49 years of age at the time of his death. He was educated at Owens College and Trinity College, Cambridge, from which latter place he was graduated in 1871 as Senior Wrangler. While an undergraduate at Cambridge he graduated as doctor of science at London University. In 1872 he joined Messrs. Chames Bros. & Company's light house works at Birmingham as engineer and introduced many improvements, notable among which is the group flashing apparatus. It may safely be said that Dr. Hopkinson has designed a greater number of special forms of light house apparatus than anyone else, and with uniform success. After 1878 Dr. Hopkinson devoted a great deal of his leisure time to scientific research. His work in dynamo electric machines and subjects allied thereto, was begun in 1879. During his experiments with a Siemens machine he introduced the method of the characteristic curve. In 1883 he made the well known improvements on the Edison dynamo and was appointed lecturer at the Institution of Civil Engineers. During the next few years he worked out the theory of the dynamo machine on a thoroughly satisfactory basis, which he published in conjunction with his brother, Dr. E. Hopkinson. This method of predetermination in dynamo design has become standard.

Dr. Hopkinson was elected a fellow of the Royal Society in 1878. He was a member of the Senate of London University, of the council of the Institution of Civil Engineers and Mechanical Engineers, and was president of the Institution of Electrical Engineers in 1890. In this year he also received one of the medals of the Royal Society. In 1895 he again accepted the presidency of the Institution of Electrical Engineers. Besides his scientific researches Dr. Hopkinson had found time to design several large electric lighting installations principal among which should be mentioned the very successful stations at Manchester and Whitehaven. He also designed electric railway systems for the Corporation of Leeds, as well as those of Liverpool and St. Helens. He did besides a vast amount of consulting engineering, all of which has turned out as successful as every labor with which Dr. Hopkinson was connected. Dr. Hopkinson's memory will be cherished by a large number of friends on this side of the Atlantic.

War Inventions.

WAR has its humorous, as well as its serious aspects. Among the former none have proved more diverting than the schemes evolved by ambitious inventors to wipe the enemy off the face of the earth. One of the latest of the frightful engines of destruction put forward is that of Dr. S. F. Emmens, of "Emmensite" fame. This gentleman proposes to build an electric gun consisting of a series of solenoids, which are successively energized and through which the projectile loaded with high explosives is sucked at an increasing velocity. One of the daily papers represents this fearful and wonderful gun mounted on a long railway carriage with the destroying projectile emerging from the last solenoid, apparently bent on frightful destruction. We think it is hardly necessary to go into the calculation of the size and number of the solenoids required to give the projectile velocity sufficient to permit it to cover a given range, but a slight contemplation of the subject will at once indicate its utter impracticability. Besides long before Dr. Emmens conceived the idea, others had hit upon it, and, indeed, we know as a matter of fact that such a gun was actually constructed on a small scale nearly twenty years ago.

The Stone Telephone Repeater.

A patent has recently been issued to Mr. John S. Stone, of Boston, Mass., on a telephone repeater or relay, which embodies novel and ingenious features. It belongs to that class of apparatus in which are combined in a single instrument the variable pressure contacts of a microphone transmitter, the electromagnet of a magneto receiver, and a diaphragm or vibratory plate, these being so arranged that in operation the diaphragm shall vibrate in response to the talking currents traversing one telephone circuit and manifesting themselves in the action of the receiving magnet and shall communicate its vibrations to the transmitting contacts, producing thereby similar talking currents in a second telephone circuit, with which the transmitting contacts are connected.

Mr. Stone's relay is adapted to be placed at the junction of two telephone circuits extending from different terminal stations for the purpose of automatically repeating the conversation transmitted over one circuit into the other and consists of a telephone receiving or repeating magnet in one circuit, transmitting electrodes or microphonic contacts in another circuit, a diaphragm common to the magnet and transmitting electrodes placed in operative relation to both, so as to act as a receiving diaphragm for one circuit and a transmitting diaphragm for the other, and a vacuum chamber or exhausted receiver inclosing the receiving magnet, transmitting electrodes, and diaphragm.

Referring to the figures, B is an electro magnet whose poles are in proximity to the diaphragm referred to further on.

C is the button of a variable resistance transmitter containing

STONE TELEPHONE RELAY IN CIRCUIT AND VERTICAL SECTION OF TRANSMITTER BUTTON.

the transmitting electrodes—in this instance two plates m and m' , with granulated carbon r between them, the plate m being secured to the diaphragm and vibrating with it and the plate m' being rigidly secured to the frame or back plate; D , the common diaphragm, and E the vacuum chamber. The magnet, electrodes, and diaphragm are inclosed in the vacuum chamber, and the whole is mounted on a base b .

The support a , secured to the base b , has an opening through its upper part, provided on one side with a shoulder or offset forming a seat for the diaphragm, which is held in place by the cap-piece A , or in any preferred manner. The transmitting button placed in the opening is attached on one side to the centre of the diaphragm D and on the other side to the plate or bar i , which, if of such shape as to close the opening, is perforated with the holes k , so that the atmosphere on both sides of the diaphragm shall be of the same density.

The receiving or repeating magnet B is mounted upon an arm c of the support a , being adjustably clamped to it by a screw d , and its poles are brought into proximity to the outer face of the diaphragm, which is thus placed between the magnet and the transmitting electrodes.

The exciting coils of the magnet B are connected with the conductors 4 and 5, which form the instrument portion of a telephone circuit extending either directly or inductively by means of the induction coil I and two circuit sections L^1 and L^2 from a subscriber's transmitter T . In the latter case 11 is the transmitter battery, p is the primary helix of the induction coil in the circuit section L^1 , and s is the secondary helix, placed in the circuit section L^2 . The transmitting electrodes C are similarly connected by means of the conductors 2 3 in a second telephone circuit L^3 , which extends to the receiving telephone t , this circuit also being shown as having two sections L^4 and L^5 united by an induction coil I' .

The vacuum chamber or exhaust receiver E may be of glass, and since in the normal operation of the relay it is required that the transmitting electrodes and diaphragm shall be surrounded by a rare medium less dense than air at atmospheric pressures a pipe P passes through the base b to connect with an air exhausting pump (not shown) for the purpose of producing a vacuum or of rarefying the air within the chamber E to the degree required. The passages through which the electrical connection wires 2, 3, 4, and 5 and the exhaust pipe p enter the chamber E are of course sealed, packed, or otherwise made air tight.

To more perfectly attain the desired result of highly efficient relayed transmission, the diaphragm D may be balanced or subjected to like normal attractive strain in both directions. This may be accomplished by employing two receiving magnets, mounted on the two sides, respectively, of the diaphragm on the supporting arms. The coils of these magnets are placed in the same circuit and are so relatively connected up that the same current impulse which strengthens the attraction exercised by one of the magnets upon the diaphragm shall weaken that of the other, so that the two magnets will uniformly work together, each aiding the other in producing all of the appropriate diaphragm vibrations. When two magnets are employed in this way, it is convenient to associate with the diaphragm two soft iron armatures, one for each magnet, these being mechanically united to one another by light metal rods and by another rod to the diaphragm.

The Telegraph in Porto Rico.

The War Department has received advices from Porto Rico on the work being done by the little army of Signal Service men on the island. There are 300 of these men now there, and they will have to assume the control and operation of the Government lines of telegraph. The lines now, of course, are operated by Spaniards, but when the possession of the island is transferred to the United States the Signal Service will have to take charge until the future status of the system is determined.

The Government has always been opposed to a governmental telegraph system, and Signal Service officials say it is not improbable that the lines in the new island possession will be eventually sold through bids for its purchase. This, however, has not yet been considered officially, and governmental control will have to be assumed, at least until the ultimate disposition is determined, at all the offices on the entire telegraph system of Porto Rico.

Blue-print diagrams of the system have been forwarded to the Signal Service authorities. They show that, aside from a line that runs irregularly along the coast, there are two lines running directly north and south, and others forming a network through the island. The principal telegraph stations which the Signal Service will have to man are at San Juan, from which there is also a double line to Caguas; Ponce, from which there is also a double line to the shore; Mayaguez, Yauco, Guayama, Arroyo, Hemacao, Farjado, Aguadilla, Arecibo, Utuado, Rio Piedras, Cayey, Aibonito and Ciales.

While there is much work to be done in the way of extending and operating the telegraph lines in the newly acquired possessions, Signal Service officials say there is no difficulty in securing enough men. Of the 300 men now in Cuba, it is claimed two companies could be withdrawn for other fields without detriment. A number of the volunteers in the corps have asked to be discharged, and where their requests are well founded they will be complied with.

Colonel Allen, Chief Signal Officer on General Miles' staff, who has been in charge of the Signal Service work in Porto Rico, has wired that he will sail from Ponce for the United

States. He is in poor health and is coming back to recuperate. Lieut. Col. Glassford, next in rank, will take command of the Signal Corps on the island.

Municipal Telephony in England.

It is stated that the select committee on the telephone service in Great Britain have agreed by a majority to recommend that the post-office shall grant licenses to municipalities on the same terms as it does to the National Telephone Company—that is to say, 10 per cent. of the rentals charged to customers.

Some Recent X-Ray Work.

The following items appear in "Science Abstracts," published by the Institution of Electrical Engineers and the Physical Society, London.

CATHODE RAYS. E. Wiedemann and G. C. Schmidt. Cathode rays are usually present in two different forms; first, the ordinary slightly conical beam forming a solid cone of rays, and secondly the beam diverging from about the same point as the other, but in the form of a conical mantle forming rings or ovals where it meets the tube. The authors have here investigated the cause of the latter and the influences which regulate its form. Its cause is attributed to rapid oscillatory discharges; and in the experiments the authors used tubes without electrodes, and excited discharges in them by means of a Lecher system of wires. The electrodes consisted of balls or rings pressed against the outside of the tube. The angle of the cone of rays diminishes with the curvature of the glass, increases rapidly with the curvature of the electrode, and increases rapidly with diminution of pressure of gas. The authors suggest the following explanation of these and all similar phenomena:

1. Rapid oscillatory discharges in rarefied gases take place near the surface as in metal conductors, but in gases are prevented from reaching the surface by the walls of the tube acting as a cathode, the discharge being thus separated from the walls by a dark cathode space.

2. The cathode rays leave the surface between the solid and the gas in the direction in which the oscillatory discharge is penetrating that surface. In air at atmospheric pressure the direction in which the oscillations leave a conductor is perpendicular to the surface of the conductor, so that if a metallic sphere is laid against the tube the cathode rays start perpendicular to the surface of the sphere. The angle of the cone only reaches a certain magnitude, owing to the distance between the sphere and the gas in the tube being too great beyond that angle. This critical distance is attained at a smaller angle the greater the curvature of the sphere.

If the metal is surrounded by rarefied gas, as is the case with internal electrodes, then the dark space influences the direction in which the oscillations leave the cathode and cause it to be no longer perpendicular to the surface.

ELECTROSTATIC PROPERTIES OF CATHODE RAYS. P. Lenard. Experiments carried out on the lines of those made by J. J. Thomson and W. Wien, lead to the result that cathode rays behave in every respect as if they consisted of moving particles possessed of inertia and conveying negative electric charges. Cathode rays emerging through a "window" and entering an observation-space is a perfect insulator. When a field is created between two condenser-plates in the observation-space, the rays are bent towards the positive plate. Those rays which suffer the strongest magnetic deflection also undergo the strongest electric deflection. The velocities of the various rays differ a little. They are probably about one-third of the velocity of light.

NODES IN CATHODE RAYS. E. Wiedemann and A. Wehnelt. When a magnet is placed opposite the cathode of a vacuum tube, or the latter is enclosed in a solenoid, the lines of force are parallel with the rays, and the latter are twisted into a succession of loops or segments which bear some resemblance to those of a vibrating string. The phenomenon may

be fully explained by the projected-particle theory of cathode rays. The feebler the field, and the higher the velocity of projection (i. e., the potential and the exhaustion), the longer are the corresponding segments. The glow-light is not similarly affected.

VISIBILITY OF ROENTGEN RAYS. E. Dorn. That the light effect of Röntgen rays is not due to an act of "accommodation" as has been alleged, has been proved by the author with the aid of a medical friend, who intentionally paralyzed the accommodation capacity of one of his eyes with homatropine, and found the visual effect as strong as before. The fact that a straight rod sometimes casts a bent shadow into the eye is explained by considering that Röntgen rays are not refracted by the humors of the eye. The rods therefore cast straight lines on the retina, which are ordinarily only produced by bodies bent in a certain manner. The straight lines are therefore interpreted as being due to bent rods.

URANITE RAYS. E. Villari. The paper describes experiments on the property possessed by uranite of discharging electrified bodies. The electrified body was a gold-leaf electroscope, which lost from leakage 1 deg. in 90 seconds. On placing a piece of uranite 1 cm. from the electroscope-knob the loss was 1 deg. in 7 seconds. Sending a current of air transversely between the knob and the uranite slightly reduced the loss to 1 deg. in 8 seconds. To ascertain to what extent the discharging power persists, the uranite was placed in a tube 20 cm. from the electroscope. This lost 1 deg. in 24 seconds when a current of air or of illuminating gas was directed through the tube against the electroscope knob. Increasing the distance to 190 cm., the loss was 1 deg. in 54 seconds. The loss without the uranite was 1 deg. in 148 seconds. Further the author found that when a metal point was placed in the air current, the phenomena were the same as in the case of gas subjected to Röntgen rays. Without the uranite and with the point to earth, the loss was 1 deg. in 134 seconds; with the uranite, 1 deg. in 25 seconds. With electroscope and point charged to opposite potentials, 1 deg. in 43 seconds; to similar potentials, 1 deg. in 156 seconds. If, however, the charged point were close to the end of the tube and nearly equal in size to its diameter, the discharging power was entirely lost. When the uranite was closed in a paper envelope no action was observable, though an image was obtained on a sensitive plate through black paper after an exposure of twenty-four hours.

Apparatus for Illustrating Change of Phase Produced by Inductance or Capacity.¹

BY SIDNEY T. MORLAND.

THE apparatus consists of a divided circuit having in each branch a conductor arranged to vibrate freely and with delicate means of adjusting its tension. This conductor is stretched between the poles of a strong magnet. The tension is so adjusted as to make the period of vibration of the conductor agree with the period of the alternating current which traverses the conductor; under these circumstances the conductor vibrates. A small mirror is attached to one end of each of the stretched conductors, and these conductors are placed at right angles to each other in such position that a small beam of light is reflected successively from the two mirrors, one of the conductors being horizontal and the other vertical. We suppose the beam of light to be received directly by the eye after reflection by the last mirror.

Now, if only one conductor be allowed to vibrate, say the horizontal one, the eye will see a horizontal band of light instead of a spot; if only the vertical conductor be allowed to vibrate the eye will see a vertical band of light; if the two vibrate at the same time, and if the two branched circuits are exactly alike in all respects, the eye will see a straight band of light lying between the horizontal and the vertical position; that is, the resultant vibration is a straight line.

¹Read before the A. A. A. S. Abstract.

Now, if a coil of wire having an iron core is introduced into one branch of the circuit and not in the other, theory shows that the phase of this branch will lag behind the other and that the resultant vibration will now be not a straight line, but an ellipse. The apparatus shows the ellipse. If a condenser is substituted for the coil the apparatus again confirms the theory in showing an ellipse. Theory also shows that, whereas, the coil causes the conductor to lag behind, the condenser causes it to advance ahead of the other conductor. In other words, if the complete ellipse is made in one case by a spot of light circulating in the direction of the hands of a watch, in the other case it is made by a spot circulating in the opposite direction. In order to show whether this is the case the beam of light is made to pass first through a small hole and then through a slit attached to a prong of a tuning fork in such a way that when the fork is vibrating the light can only fall on the mirrors when the fork is passing the position of rest; in other words, the light is regularly intermittent.

By means of sliding weights on the prongs of the fork its time of vibration can be adjusted so as to make exactly one vibration while the conductors make two. Instead of seeing a complete ellipse the eye now sees an arc which is stationary. If the time of vibration of the fork be very slightly increased the arc will move around slowly in the direction in which the spot actually travels.

Having made this adjustment and having observed the direction in which the arc travels, if the condenser be substituted for the coil it will be observed that the direction in which the arc travels is changed. Thus the apparatus shows that either an induction coil or a condenser will cause a change of phase, and that these changes are in opposite directions.

The Commutated Current Wave of a Composite Wound Alternator.¹

BY PROF. D. C. JACKSON.

THE accompanying curves were taken by Mr. H. S. Webb, one of my graduate students, during a relative study of the current and pressure waves in the various branches of a 50 kilowatt alternator with composite winding. The normal pressure of the alternator is 1,100 volts, and the frequency is 125 periods per second. The machine was built several years ago by the Thomson-Houston Electric Co., and has the usual construction of the old belt-driven alternators with ten field poles and a toothed core, ribbon-wound armature. The driving speed during the tests was quite unsteady, as the machine was driven by the same engine that drove two street railway generators: and this resulted in irregularities which are evident in the curves.

FIGS. 1 AND 2.—PRESSURE AND COMMUTATED CURRENT WAVES WITH LOAD OF 22 AMPERES.

I am not acquainted with any results which have heretofore been given in the Transactions of the Institute or elsewhere, which show the characteristic form of the commutated current waves in the series field of an alternator, and I therefore present these curves. The question of the form of the commutated current wave is mentioned in two or three text books, but experimentally determined waves do not appear.

In the series of curves presented herewith, Fig. 1 is the pressure wave when the armature current equalled 22 amperes. A comparison of Fig. 2 shows the wave of commutated current in the series field when the external current equalled 22 amperes.

A comparison of the external current waves, with the commutated waves, shows that the commutated waves have practically the same form as the original waves of current (with alternate loops inverted) except in regions occupying about 25 degrees on either side of the zero points of the original waves.

¹Read before the A. I. E. E. Abstract.

Within these regions the commutated waves do not come to zero and they take a characteristic toothed shape, as is to be expected from the effect of the self-induction of the field windings when they are short-circuited by the brushes on the commutator. There does not appear to be any immediate connection in this machine between the pulsations of the series field current and of the current in the separately excited field. The latter pulsations are, in fact, sufficiently accounted for through the effect of the rotation of the toothed armature and the effect of armature reactions.

The points on these curves were located by a balance or potentiometer method similar to that described on pages 296 and 297 of Jackson's "Alternating Currents," but, instead of the usual galvanometer or telephone receiver, Mr. Burgess' portable form of capillary electrometer recently described was used to indicate the point of balance. This instrument has been used in tracing alternating current curves by quite a number of my students, and it is the unanimous verdict that the instrument greatly increases the convenience, the accuracy, and the speed of the method. We have had a number of the instruments in use during the past winter and have found them perfectly portable, difficult to injure, and practically unaffected by external influences.

Capt. Robert Edwards, Jr.

We are pleased to note the fact that on August 20 Messrs. Edwards & Co., manufacturers of electrical goods, 144th street, New York, have learned from Capt. Robert Edwards, Jr., that Company B, Eighth New York Volunteers, now at Chickamauga Park, has enjoyed good health in camp from the beginning. Of the 104 men in his company, we deplore the fact that 59 are on the sick list, over 35 of them having typhoid or cerebral meningitis, and should the Eighth be compelled to make the march through Georgia, as ordered, it is thought that hardly more than 25 could comply with the orders. Capt. Edwards' wife has been near the camp all summer.

SOCIETY & CLUB NOTES

Meeting of the N. Y. State Street Railway Association.

The annual meeting of this association will be held at Manhattan Beach, Coney Island, N. Y., on Sept. 13 and 14. A number of interesting papers have already been submitted and the topical discussions promise to elicit much useful information.

Association of Edison Illuminating Companies.

The annual meeting of this association will be held at Sault Ste. Marie on Sept. 11, 12 and 13. Quite a number of the members will leave Buffalo on the steamer "North West" on Sept. 9, and make the lake trip to the Sault. Headquarters will be at the Iroquois Hotel.

Eighth Annual Meeting of the American Electro-Therapeutic Association.

The eighth annual meeting of the American Electro-Therapeutic Association will be held in Buffalo on the 13th, 14th and 15th of September. The business meetings of the association will be held in the rooms of the Buffalo Society of Natural Sciences, in the Public Library Building. Among the papers to be presented are some by the most noted writers on medical topics in this country and Europe, among which might be mentioned Drs. Apostoli and Gautier, of Paris, Dr. La Torre, of Rome; Dr. J. I. Parsons, of London; Mr. Nikola Tesla, of New York, and a number of others of equal prominence. The papers embrace the entire field of electro-therapeutics and will make the convention of great interest and value. A public exhibition of electrical apparatus for diagnostic, radiographic and therapeutic work will be held in the library, and a large number of enter-

tainments have been provided for. Special hotel rates have been secured at Niagara Falls as well as in Buffalo for all attending the convention.

Classified Digest of U. S. Electrical Patents Issued August 23, 1898.

Alarms and Signals:—

BURGLAR ALARM. D. L. Wartenluft, Kutztown, Pa., 609,640. Filed Nov. 18, 1897. Comprises an electric circuit, the wires of which are extended across a window, an alarm in the circuit, and a circuit closer mounted to swing on one of the wires and adapted to close the circuit when swung out of its normal engagement with the window.

APPARATUS FOR SIGNALING ON LOCOMOTIVES. F. A. Cheetham, Rastrick, and R. Bostock, Brighouse, England, 609,732. Filed Jan. 18, 1898. Details of construction.

Electro-Metallurgy:—

ALLOY OF IRON AND TITANIUM AND PROCESS OF PRODUCING IT. A. J. Rossi, New York, 609,466. Filed June 5, 1896. A compound containing not less than 10 per cent. of iron, some carbon, and titanium in proportions of not less than 5 per cent.

PROCESS OF MANUFACTURING ALLOYS OF TITANIUM. A. J. Rossi, New York, 609,467. Filed Oct. 16, 1897. Similar to above.

Electro-Therapeutics:—

ELECTRICAL APPLIANCE FOR ASSISTING ANATOMICAL ORGANS. J. Doty, Syracuse, N. Y., 609,914. Filed March 22, 1898. Details of construction.

ELECTRO-MEDICAL APPARATUS. R. H. Wappler, New York, 609,639. Filed Nov. 2, 1897. Comprises a rheostat coil, two sliders, a shaft, cranks and connections for moving the sliders in opposite directions, a hand upon the crank shaft and a dial for indicating the action of the rheostat in the electric circuit.

Lamps and Appurtenances:—

DEVICE FOR ATTACHING AND DETACHING ELECTRIC LAMP BULBS. C. G. Edwards, Albert Lea, Minn., 609,421. Filed Aug. 23, 1898. Consists of a rotatable handle, a holder for engaging with the bulb and connecting with the handle, and a guard extending out from the handle.

Miscellaneous:—

FIELD-SPOOL-WINDING MACHINE. W. Leist, Norwood, O., 609,620. Filed Aug. 14, 1897. Comprises a support, two parts mounted on the support, namely, a rotatively mounted frame provided with means for removably supporting a supply spool and a carriage having means for moving one of the parts relatively to the other part in a direction parallel to the axis of rotation of the frame.

MANUFACTURE OF FLUID FOR IMPREGNATING FIBERS FOR INCANDESCENT LIGHTING. G. B. Puchmüller, Schöneberg, Germany, 609,702. Filed March 21, 1898. Employs a fluid consisting of oxides of strontium, zirconium, barium and aluminum.

DIAPHRAGM FOR ELECTROLYTIC PURPOSES. W. G. Luxton, Liverpool, England, 609,745. Filed April 9, 1898. A composition of cement, sand and a porous material mixed with water and allowed to dry, the diaphragm having pores through the substance of the porous material and interstices between the cement and other constituent particles.

Classified Digest of U. S. Electrical Patents Issued August 30, 1898.

Conductors, Conduits and Insulators:—

CLAMP FOR ELECTRIC WIRES. S. S. Leonard, Chicago, Ill., 609,888. Filed Jan. 24, 1898. A clamp consisting of a flexible loop adapted to embrace the glass insulator and a pair of clamping blocks loosely secured to the loop at one end and each provided at the other end with a notch adapted to receive the free end of the wire, that end being provided with means for clamping it upon the blocks.

Dynamos and Motors:—

ALTERNATING CURRENT MOTOR. C. S. Bradley, Avon, N. Y., 610,025. Filed Sept. 17, 1897. Includes a primary winding provided with a plurality of branches, including inductance to set up in the primary core a rotary field when connection is made with a single-phase current, and a secondary element, the windings of which are connected with an adjustable phase leading device.

INDUCTION MOTOR. B. G. Lamme, Pittsburg, Pa., 610,067. Filed July 22, 1897. Embodies a secondary member, comprising a spider, a laminated slotted core, bar conductors located in the core slots and projecting beyond the ends of the same, and resistance rings provided with ventilating and centering blades which are bolted to the inner sides of the projecting ends of the bar conductors, and have shoulders bearing against the adjacent portion of the spider.

Electro-Metallurgy:—

PROCESS OF EXTRACTING METALS FROM METALLIC OXIDES. H. C. Aschermann, Cassel, Germany, 610,014. Filed April 20, 1897. Consists in adding to such oxides the sulfide of antimony in greater proportions than the oxides, and then subjecting the mixture to electric currents.

Electro-Therapeutics:—

ELECTRODE FOR MEDICAL PURPOSES. M. N. Clarke, Wilkes-barre, Pa., 609,876. Filed Jan. 8, 1898. A suitable source of electricity and a pair of electrodes, consisting of metal plates filled with small perforations.

Lamps and Appurtenances:—

HANGER FOR ELECTRIC LAMPS. W. F. Murphy, Iowa City, Ia., 609,972. Filed Dec. 21, 1897. Details of construction.

Miscellaneous:—

PROCESS OF AND APPARATUS FOR PRODUCING CALCIUM CARBID. M. P. Wood, New York, 609,864. Filed April 23, 1897.

Consists of forming a mixture of the pulverized mineral and carbon with a suitable binder into a cartridge; subjecting the cartridge to the direct heat of a combustion-furnace and passing an electric current through the cartridge while still subjected to the heat of the furnace.

Railways and Appliances:—

ELECTRIC LOCOMOTION. H. Van Hoevenbergh, New York, 609,851. Filed Oct. 10, 1895. A trolley having spring-pressed contacts, and conductors for connecting with a vehicle, the conductors being mounted on the frame by a laterally movable connection.

TROLLEY. D. Lippy, Mansfield, O., 609,969. Filed Feb. 23, 1898. Details of construction.

ELECTRIC RAILWAY MOTOR. A. Schmid, Pittsburg, Pa., 609,977. Filed May 10, 1894. Comprises an armature, a field magnet constructed in two sections, the upper section being supported by the car truck and the lower section being hinged to and supported by the upper section and adapted to swing downward.

RAIL BOND. W. H. Talley, Waco, Tex., 610,004. Filed Nov. 28, 1897. Comprises a suitable rail having a base angle bar located on either side and having basal flanges, normally in contact with the base of the rail, angular-shaped grooves formed in the basal flanges of the angle bars, and triangular conducting bars located in the grooves.

CONTACT DEVICE FOR ELECTRIC RAILWAYS. L. W. Walkins, Springfield, Mass., 610,007. Filed Jan. 24, 1898. Underground conduit system embodying roller contacts.

CONTACT RAIL APPLIANCE FOR ELECTRIC RAILWAYS. L. E. Walkins, Springfield, Mass., 610,008. Filed Feb. 2, 1898. Similar to above.

ELECTRIC RAILWAY. L. E. Walkins, Springfield, Mass., 610,009. Filed Feb. 2, 1898. Similar to above.

ELECTRIC RAIL BOND. B. C. Seaton, St. Louis Mo., 610,000. Filed April 5, 1897. The conductor is carried between the rails by an insulating support and housing, composed of two members arranged one above the other, and suitably fastened together, the conductor being clamped between the two members.

THIRD RAIL FOR ELECTRIC RAILWAYS. B. C. Seaton, St. Louis, Mo., 610,001. Filed Dec. 7, 1897. The rail is formed with a channel in the upper side to receive feed-in wires.

CONTACT DEVICE FOR ELECTRIC RAILWAYS. B. C. Seaton, St. Louis, Mo., 610,002. Filed Feb. 4, 1898. The combination comprises a hanger having a head secured to it, a frame pivoted to the head, a shoe secured to the frame, and a spring for holding the frame in a horizontal position.

THIRD RAIL FOR ELECTRIC RAILWAYS. B. C. Seaton, St. Louis, Mo., 610,003. Filed Feb. 4, 1898. Comprises a conductor having a vertical flange providing an exposed surface for the contact shoes and a lateral flange, providing a guard for the contact shoes.

ELECTRIC RAILWAY. B. C. Seaton, St. Louis, Mo., 610,004. Filed Feb. 18, 1898. Comprises a third rail in combination with a crossing located in a gap in the third rail and consisting of a hood, bars supporting the hood, and a conduit enclosed by the hood and bars.

Regulation:—

MEANS FOR CONTROLLING NON-SYNCHRONOUS ALTERNATING MOTORS. B. G. Lamme, Pittsburg, Pa., 609,990. Filed March 11, 1898. A variable speed, non-synchronous motor having a comparatively large secondary resistance and a small degree of magnetic leakage between its primary and secondary members, and means for varying the electromotive force applied to its primary member, whereby the speed of the motor is varied.

METHOD AND MEANS FOR SECURING CONSTANT TORQUE IN POLYPHASE MOTORS. B. G. Lamme, Pittsburg, Pa., 609,991. Filed Feb. 10, 1898. An induction polyphase motor having a comparatively high resistance secondary winding and small magnetic leakage combined with choke coils in the external circuit, the cores of which become saturated by a given current whereby a constant torque is secured.

Switches, Cut-Outs, Rheostats, Etc.:—

CONTROLLING DEVICE. K. A. B. D. Kottgen, Charlottenburg, Germany, 610,064. Filed Dec. 30, 1897. Designed for the operation of hoists. Details of construction.

CONTROLLER FOR ELECTRIC MOTORS. H. P. Davis, Pittsburg, Pa., 610,124. Filed April 25, 1898. In a controller for electric motors, the combination comprises a resistance-varying switch, and a series-parallel switch, the shafts of the switches being at right angles to each other; gearing between the shafts, combined cut-out and reversing switches and interlocking mechanism.

ELECTRIC CIRCUIT CONTROLLER. J. H. Bowley, Washington, D. C., 11,689. Reissued. Filed Nov. 9, 1897. Means for the control of atmospheric conditions in food-storing chambers.

Telephones:—

TENSION REGULATOR FOR ELECTRICAL TRANSMISSION OF SPEECH. A. C. Cousens, Newark, N. J., 609,877. Filed June 15, 1895. Consists in subjecting to the action of the transmitting current, a substance from which is thereby generated, a gaseous variable resistance medium, and varying the resistance of the gaseous medium by the action of and to conform to the sound waves to be transmitted.

AUTOMATIC CUT-OUT FOR MAGNETO GENERATORS. W. J. Bowen and C. A. Federer, Cleveland, O., 610,023. Filed May 28, 1898. Consists of a spindle carrying a loose wheel and an insulating projection rigidly secured to the spindle, a pin-and-slot connection between the wheel and projection, a contact plate on one of these parts, and a spring arranged to hold the pin in contact with the plate.

Theft of Current at Erie, Pa.

The "Erie Dispatch" says: "A warrant issued by Alderman McAndrew has been served on Leo Gieringer, of 1712 Peach street, at the instance of the Edison Electric Light Company, whereby that party is cited to appear on a criminal charge, the offence being nothing more nor less than the alleged stealing of lightning. The information charges that Gieringer, who is a confectioner, has attached a wire to the Edison Company's feed wire which passes his place and that he has been running a motor for a year or more, to say the least, surreptitiously, that is, without the knowledge of the prosecuting company, and has been using the current generated and sold by the Edison people. The allegation is that Gieringer has been running a fan to cool the fevered brows of his customers."

TRADE NOTES AND NOVELTIES

The Moloney Electric Company's Type A Transformers.

THE need of greater economy in alternating current distribution is being daily pressed upon the attention of those in charge of central stations. Within the past few years the importance of increased operating efficiency in transformers has become plainly evident to them, and a closer investigation of existing systems and apparatus has been generally instituted.

A company who have constantly endeavored to promote the spirit of inquiry is the Moloney Electric Company, located at No. 6 North Twelfth street, St. Louis, Mo., who have placed on

MOLONEY ELECTRIC CO.'S TYPE A TRANSFORMER.

the market a thoroughly up-to-date transformer covering every desirable feature of economic distribution which experience has thus far suggested in the construction of transformers. Their claims of merits have been amply borne out by severe tests to which the transformers have been subjected. The following is a description of the company's Type A transformer and the advantages claimed for it:

In the company's Type A transformer the core and copper losses have been reduced and the maximum all-day efficiency has been greatly increased. Close regulation is a salient feature of the Type A transformer. Regulation depends on the copper loss and magnetic leakage. Copper loss is reduced by lessening the resistance of the coil, which is done by using a wire comparatively large for the current it has to carry. But to diminish the effect of magnetic leakage is more difficult of accomplishment. In the Type A transformer, however, by the peculiar construction of the core and windings, this effect is practically nullified. In fact, so insignificant is the magnetic leakage in this transformer that it is hardly discernible under the severest test, and as to the C'R loss, it has been reduced to a point which long practice and experience have demonstrated to be the most efficient for all practical purposes.

Sometimes a transformer of very low resistance is in requisition for special laboratory work. In such cases the company will construct "special" transformers to meet the specifications given.

Alternating current circulating in the coils, the wires are attracted and repelled at a rate of about 100 times to the second. This ceaseless attraction and repulsion of the wire soon pulverizes the insulation, and the turns of the coil come in contact;

injury to the apparatus follows where the coils are wound loosely with a packing of some insulating material.

How to remedy this condition of affairs has been a leading consideration in the construction and designing of the company's transformer, and they claim to have successfully attained their purpose: (1) By compressing the cores under very high pressure, which is made possible by their construction, (2) by winding the wire on the coil under very high tension, (3) by using only the very best insulation. In this way they have shut off all possibility of vibration either in the wires or the iron, a proof of which is the absence in these transformers of that sizing sound that betokens the deteriorating effects of vibration.

A very necessary requirement in transformer insulation is the unchanging durability of the substance to be employed. Oil has been freely advocated. Experiments with oil made by the company have proved it to be a very unsatisfactory insulating medium. They are not, however, wholly against the use of oil as an insulator. On the contrary, they are of the belief that in transformers of lower voltage it may be used to advantage, provided the supply is renewed every six months or so. But these, of course, are not conditions to be expected in general practice.

Their experiments with cloth (oil cloth, linen, etc.) and paper have convinced them that these are not materials to be used in first-class transformers, as they deteriorate with age. The company's patent insulation has been so devised as to withstand the effects of a very high temperature and the vicissitudes of age, whether in actual use in the transformer or on the shelves of their storerooms.

The case of this transformer has been made with a view to convenience as well as safety. The eye-bolt on the top exactly in the centre makes it easy to raise, while the terminals on the buttons prevent short-circuitings in the bushings and facilitate connection.

Lost energy in a transformer manifests itself by the presence of heat, for the radiation of which some disposition must needs be made. The Type A transformer has been so constructed that most energy is lost on the outer surface, whence the heat is easily dispelled through the ventilating slots. This construction has the result that there is comparatively little increase in temperature while the transformer is under full load or even under a considerable overload, a feature characteristic of the Type A transformer.

All iron is liable to deterioration, but in the finer kinds the process of ageing is so slow that it can be perceived with difficulty. After repeated tests, in which the company spared neither effort nor money, they have succeeded in securing for the manufacture of their transformers an iron, in which even after a constant use of eighteen months, scarcely a trace of this degeneracy is discernible. In this respect, as in all others, they are ready to guarantee Type A transformer for a term of two years.

MOLONEY ELECTRIC CO.'S TYPE A TRANSFORMER.—COVER REMOVED.

They have designed a "lightning arrester" to protect the circuits on which their transformer is used, and have never hesitated to guarantee their customers against damage by lightning where the line is safeguarded by this or any other approved pattern of arrester.

The company have amply provided for emergencies, so constructing their transformers that they will bear an overload of from 25 per cent. to 30 per cent. for an indefinite length of time. To this point they call attention in their contract, and offer an especial guarantee for the fulfillment of this condition. All transformers are interchangeable for 1,000 to 2,000 volt primary.

Work in central stations may sometimes, from its very nature, require a special design of transformer. The company manufacture all such specialties. Series transformers, for series incandescent and arc lighting, "step-up and step-down" transformers, test transformers, etc.

The test transformer consists of one subdivided transformer (step-up) from 1,000 to 10,000 volts, and one subdivided regulating transformer of 100 to 200 volts.

They will turn out these apparatuses in conformity with any given specifications. In cases where extraordinary precaution is required to insure against the connection of the primary and secondary windings, they furnish the "Ground Shield" transformer. This shield is a simple tegument of copper, which completely envelops the secondary coil and from which it is thoroughly insulated as well as from the primary. It is grounded so that any rupture in the insulation of the primary coil will connect it with the earth, thus protecting the secondary from the high-tension current of the primary. This model is not intended for general use and is recommended only in cases where such extra precaution is advisable.

The company also manufacture arc light Type B transformers, which they always carry in full stock and of all sizes and voltages.

These transformers are of the same high grade as Type A, and are subjected in their manufacture to the same rigid tests as a guarantee of their superior efficiency and durability. They are set up in either ornamental or plain iron cases for either indoor or outdoor use.

Fig. 1 shows a perspective view of the Moloney transformer; Fig. 2, a view of the core and coils, the cover being removed, and Fig. 3, curves of efficiency plotted from figures obtained from actual tests. Curve A shows the maximum efficiency at 133 cycles; Curve B, maximum efficiency at 60 cycles; Curve C, all-day efficiency at 133 cycles, and Curve D, all-day efficiency at 60 cycles.

EFFICIENCY CURVES OF TYPE A TRANSFORMER OF MOLONEY ELEC. CO.

To make certain that their transformers in the hands of an intelligent operator are safe and prove their merits, the company publish full instructions for the handling and testing of transformers. A catalogue containing these instructions and a description of Type A transformer will be sent to anyone on application to the company.

The Thermo Electric Co's Increasing Business.

The Thermo Electric Company, which was recently organized to manufacture the improved Cox thermo generator, has lately increased the capacity of its factory to the output of 200 generators per week.

The demand for these generators for charging storage batteries for all purposes is continuously on the increase. As a source of power where a small amount of electrical energy is required, it is claimed there is nothing in the market that will equal them. A new application of the generator consists in placing the same around the exhaust pipe of gas engines, and the waste heat escaping from the engine is utilized in exploding the gas in the cylinder of the engine for the usual electric spark.

The many testimonials received from electro-platers show the

superiority of this device for this purpose. Jewelers, doctors and dentists are rapidly discovering the great advantage of this machine for operating their various electrical devices.

F. E. Homer & Company, Cleveland, Ohio.

THIS firm makes a business of building and refilling commutators for generators and motors of every type and of any size, and claim to be the only concern in the country that devotes its entire energies to this line of work. The special claims made for their products are that only the very best material is em-

COMMUTATOR WORK OF F. E. HOMER & CO.

ployed and that the method of assembling and finishing, which differs materially from old methods, insures a commutator that will be durable and satisfactory in every particular. While this practice of building only from first-class material is followed when left to their choice, they are prepared to build commutators of such material in such a manner as may be selected by the customer.

Mica insulation only is employed, so that their products are perfect in this respect, and they also make solid mica rings for all commutators. The difference in cost between first and second-

class material is strikingly emphasized by the fact that the cost of a commutator for a T.-H. D. 62 generator is \$24 more where high-grade material is employed than when other grades are used, and yet, in appearance the difference could not be detected, but the wear will tell the story, and the best is always the cheapest.

In their dealings the firm make it a practice never to sell a cast bar for a drop forging, neither do they piece the mica for segment insulation. The name of the company is a guarantee for all their work, as they have been engaged in the manufacture of commutators since 1892 and have among their customers a number of street railway companies, whose commutator work they have done for the last six years. The output, however, is not confined to commutators for street railway work, but they make all the commutators for a number of the prominent electrical manufacturing companies of the country, as well as for electric lighting companies, and especially for isolated plants.

The business was originally established in 1892 on Water street, where they were burned out, when they moved to High street, and in May, 1897, to their present quarters in what is known as a part of the old Brush works, on Belden street. The building is a one-story brick structure, one-half of which, or a

space 30 by 140 feet, is occupied by the works of this company. The power for operating the tool equipment is supplied from a 5 h. p. gas engine, and there is a 1,000-volt alternating generator for testing purposes.

The equipment consists of a very fine class of metal-working tools, some of special design, and these are supplemented by a 20-ton press for pressing the bars in place, and a portable crane or hand-lift, which is mounted on castors, and which, by means of a handle, can be moved about the shop, thus facilitating the handling of heavy commutators and heavy material. The baking, to which special attention is given, is done in a galvanized iron oven in which gas is employed for fuel. With the present equipment the shops are able to turn out a large number of commutators per week.

Recent Sales by the Ridgway Dynamo & Engine Co.

The Ridgway Dynamo & Engine Company, Ridgway, Pa., builders of automatic engines and generators, report the following sales: Stineman Bros., South Fork, Pa., one 150 h. p. engine; W. H. Brown's Son, Pittsburg, Pa., one 18 h. p. engine direct connected to one 10-kilowatt generator; H. H. Stevens, Colorado Springs, Col., one 30 h. p. engine, direct connected to 15-kilowatt generator; village of Cass City, Mich., one 125 h. p. engine; Berwind-White Coal Mining Company, two 250 h. p. engines, making seven engines of this size and three 150-kilowatt generators furnished within the last fifteen months; Schoen Pressed Steel Company, through Messrs. Manning, Maxwell & Moore, of Pittsburg, one 160 h. p. engine, direct connected to 110-kilowatt generator, this being the fourth direct connected plant furnished the Schoen people; Link Belt Machinery Company, four 150 h. p. engines; Western Coal Mining Company, Yale, Kan., one 125 h. p. engine; Collins State Homeopathic Hospital, Collins, N. Y., one 40 h. p. engine direct connected to 25-kilowatt generator and one 80 h. p. engine direct connected to one 50-kilowatt generator; Mt. Olive & Staunton Coal Company, Staunton, Ill., through the Jeffery Manufacturing Company, Columbus, O., one 180 h. p. engine; Jefferson Medical College, Philadelphia, two 100 h. p. engines direct connected to two 60-kilowatt generators. Most of this work is yet to be shipped.

The Union Boiler Tube Cleaner.

Regardless of precautions taken and due principally to the impurity of the water used, steam boilers are often made inoperative and dangerous by the scale adhering to the tubes. One of the most efficient devices for the removal of this scale has been placed on the market by the Union Boiler Tube Cleaner Company, 250 Penn avenue, Pittsburg, Pa. It consists of a flexible shaft, the core of which is composed of links made of either aluminum, phosphor bronze or steel, depending on the duty required; this is incased in square steel wire made and tempered especially for this specific purpose, which is in turn covered with leather, or preferably, specially prepared rubber, warranted to stand 300 degrees of heat, and to be unaffected by the oil, or preferably hard grease, used in lubricating the core; it can be made to meet any requirement, and in any length of section up to eight feet; the parts being interchangeable, the sections can be rapidly coupled together to make a shaft of any desired length. As to its lasting qualities; doing drastic work, it is claimed that a No. 8 shaft 21 feet long, of 1¼-inch phosphor bronze core, ran for 23½ consecutive days, of ten hours each, at 2,000 revolutions per minute, doing 10 h. p. work, in curved tubes of boilers, removing scale running from ¼ to ¾ of an inch in thickness, and of a very dense and tough quality, thereby putting an unequal strain on the core, with the result of only three links breaking in all that time. The remainder of the shaft after this crucial test was in such good condition that there was no evidence to show that it had ever been used at all; there being in actual use no wear on any part of the shaft, excepting on the links and the inner side of the wire casing, which, with the peculiar method of construction, makes an absolutely smooth interior and with the hard grease used as a lubricant does away with friction, and consequently, wear, on the links and casing to an extent that is simply astonishing. The contour of the links is such that in any position they are forced to assume they are neither affected by, nor do they affect, the slight opening formed on the one side of the wire casing while rounding a curve.

The company are prepared to make these shafts of any desired length or diameter and will be pleased to communicate with any concerns desirous of saving coal and lengthening the life of their boilers.

Popularity in Boston of Babcock & Wilcox Boilers.

That the Babcock & Wilcox boiler enjoys a deserved popularity in Boston and vicinity is evidenced by the large number of these boilers now in use in that city. The West End Street Railway Co. alone have in use 19,000 h. p. of Babcock & Wilcox boilers, distributed among their five power stations, the Central, East Cambridge, Charlestown, Dorchester and Harvard, which last station is illustrated in this issue. The Lynn & Boston Street Railway have 4,000 h. p. divided between the Chelsea and Lynn stations. The Edison Electric Illuminating Co., of Boston, 4,000 h. p., and the new station of the Boston Electric Light Co. will have 4,400 h. p. when completed, which will be in the near future. Such a showing is certainly of great credit to the Babcock & Wilcox Co. and doubtless will be favorably commented upon by the delegates to the convention in their visits to the various power houses.

Satisfactory Tests of Beacon Lamps.

For several months extensive tests have been made of Beacon incandescent lamps, the results of which have from time to time been noted in our columns. It appears from these tests that the initial candle power of the lamps is maintained beyond the time guaranteed by the company, and that the lamps have a long life and do not blacken. The guarantee is that the lamps retain their candle power for over 300 hours at small consumption of current. A test has lately been made in which a number of Beacon lamps were placed in circuit. After a number of hours half of the lamps were replaced by new ones, and it was impossible to tell which were the old and which were the new lamps in circuit. This also holds true for the series lamps for arc and incandescent circuits as well as miniature lamps.

The Duquesne Galvanizing Co.

BY A. D. McNAIR.

THE Duquesne Galvanizing Company, of Pittsburg, Pa., galvanize by a process of electroplating. There are two principal advantages in their process over the old "hot" process of galvanizing. First, the threads of bolts and nuts are galvanized without interfering with the nut screwing on properly. Second, the zinc coating never cracks or scales off, no matter how short the bend is.

The works of this company are located at Twenty-first and Smallman streets, in the city of Pittsburg, Pa., and have been in operation about six months. There is only one other works like this one in the United States.

Power is derived from a 35 h. p. "New Era" gas engine built by the New Era Iron Works, of Dayton, O. The engine uses natural gas, which is exploded by an electric spark and runs at 175 revolutions per minute. It is connected with the dynamo by counter shafting equipped with clutch to cut the dynamo out or in, as may be desired. The dynamo was built by the Otis Electric Company, of Yonkers, N. Y. It runs at the rate of 500 revolutions per minute, and gives a direct current of 2,000 amperes at a pressure of 6 volts. Owing to the low voltage, the field coils cannot be self-excited to the required degree, therefore an exciter is used. The latter runs at 800 revolutions per minute and gives a current of 5 amperes at 40 volts, the voltage and amperage in both dynamo and exciter being measured by Weston instruments. The main conductors are solid copper bars 3 inches wide and ½ inch thick.

The process of galvanizing is as follows: To remove any oil or grease that may be on the iron it is first immersed in a vat of hot caustic potash. To remove the scale which is always found on the surface of iron, it is next immersed in a vat of dilute muriatic acid, or, if the piece is of cast-iron, it is immersed in dilute hydro-fluoric acid instead. From these vats the pieces to be galvanized are taken and placed in a vat of clear water to rinse off the acid.

Next they are immersed in a "striking solution" of milky whiteness by being suspended from cathode bars, which results in their being coated with a film of tin. After another rinsing

in a tank of clear running water they are finally placed in the galvanizing vat, where they receive their final coating.

The galvanizing vat is 31 feet long, 4 feet wide and 5 feet deep. There are three anode and two cathode bars extending the whole length of the vat. The anodes proper are sheets of pure zinc, whose disintegration constantly replenishes the sulphate of zinc solution in the vat. The pieces to be galvanized are suspended from the cathode bars and are completely coated with zinc in about twenty minutes.

The final part of the process is to dip the pieces in a vat of hot water, which not only rinses them, but heats them so that they dry of their own heat.

An 8 h. p. boiler is used to heat water to keep several of the vats hot; viz., the caustic potash vat, the muriatic acid vat, the hydro-fluoric acid vat and the hot water vat.

A duplicate dynamo and galvanizing vat are about ready for use, which will double the capacity of the plant.

The process above described is not so well suited to galvanizing wire as the hot process, because it is not as expeditious, but it is better than the hot process for bolts, nuts, hoops, fence cleats for wire fences and other things too numerous to mention.

To show that the zinc coated by this process will not crack or scale, the following experiment was made before the writer: A strip of iron one inch wide and $\frac{1}{8}$ inch thick was bent double and hammered down flat, yet the coating did not crack a particle.

In cutting threads on bolts and nuts designed to be galvanized a slight allowance should be made, else the nut will go on hard. This company is already supplying bolts for water meters, hoops for beer kegs and pickle kegs and fence cleats for a wire fence company. It is probable that galvanized bolts will find ready sale to the makers of agricultural machinery, because there is no class of machinery so much exposed to the weather and which suffers so much from rust as agricultural machinery. Bolts and nuts for rails would be improved by galvanizing them.

The officers of the company are: F. K. McCance, president; W. T. McCance, secretary and treasurer; R. O. Miller, general manager.

The Albany Lubricating and Compound Cup Company.

A very interesting and complete catalogue of lubricating compounds has recently been issued by Adam Cook's Sons, 313 West street, New York. It contains a mint of information about the Albany Compound made by this company for engine, dynamo and railway lubricating purposes. The catalogue also contains illustrations of a great variety of oil cups manufactured by the company of sheet zinc, brass, glass and tin. The catalogue will be sent to any one on application.

Western Electric Company, Bulletin No. 5.

This bulletin recently issued by the Western Electric Company illustrates and gives prices of their station instruments. Their arc ammeter designed for station use is well protected by a sealed case, it has no springs or permanent magnets and it is dead beat and accurate within 1 per cent. The same can be said of their current indicator which is used to show the direction of the current. The voltmeter manufactured by this company is designed for use in dynamo switchboards and is made for voltages from 120 to 600. The magnetic vane meter is adapted to be placed directly in a circuit, no shunts or other devices being used in connection with it. The circular contains prices of all these instruments and will be sent to anyone on application.

WARREN O. The American Incandescent Lamp Company has made an assignment for the benefit of its creditors. Liabilities, \$15,000.

The American Electrical Works Clambake.

WE are pleased to note that the twentieth annual clambake of the American Electrical Works will take place on Saturday, September 10, at the Bomham Club, Narragansett Bay, Providence, immediately following the street railway convention. It goes without saying that all recipients of invitations to the clambake of the year look forward to the event with great anticipation.

The Bacon Air Lift Company.

ELSEWHERE will be found an advertisement of the Bacon Air Lift Company with offices at 100 Broadway, New York. This company was organized for the purpose of doing a general water supply and hydraulic engineering business, making a specialty of the application of compressed air for pumping water and all kinds of liquids.

The Bacon air lift pump has been on the market for more than four years, has had a large sale, and is operating at least three hundred wells, supplying water to various electric light and power plants, cities, towns, factories, breweries, etc., in different sections of the country. This company seems to have no difficulty in obtaining strong testimonial letters wherever they install plants, showing that their system is all that is claimed and gives good satisfaction.

The officers of the company are E. S. Hosmer, president; C. E. Bulk, vice-president; J. E. Bacon, secretary; John T. Gibson, treasurer, and the directors are: Henry Morton, Ph. D., president Stevens Institute of Technology, C. E. Bulk, J. E. Bacon, John T. Gibson, Col. A. A. Hosmer, Edward S. Hosmer, Geo. R. Young.

Messrs. Young and Gibson are quite well known through their long connection with the Blake and Knowles pump companies and are experienced in the matter of pumping machinery, also having been identified for the past three years with the Bacon air lift pump. Mr. J. E. Bacon has long been known as an expert in the matter of underground water supply.

Therefore, in devoting itself exclusively to the business of underground water supply the Bacon Air Lift Co. is in position to design and install well systems, also to furnish and install proper pumping machinery in connection therewith.

Interesting features of their mechanical appliances are the patents of Messrs. Young and Shaw, which are very successful and by which the field of usefulness in pumping liquids by compressed air is greatly broadened. With these inventions artesian wells may be operated when situated long distances from power houses, and at the same time the water discharged horizontally under pressure, thus utilizing sources of water supply which otherwise are beyond the possibilities of an air lift pump.

THE NORTON AND TAUNTON STREET RAILWAY COMPANY, NORTON, MASS., has been given permission by the railway commissioners of Massachusetts to issue \$80,000 in bonds to build a power house and equip its lines with electricity. The overhead trolley system will be employed, there being 14 miles of circuit of No. 00 trolley wire and 0000 feed copper. The equipment will be furnished by the Walker Company for eleven cars, two box, three duplex, and six open, furnished by the Briggs Car Company, Amesbury, Mass., and equipped with Peckham trucks. They will install two 350 h. p. McIntosh & Seymour engines, and two 350 h. p. Babcock & Wilcox boilers. The power house will be built of brick. The officers of the company are: George H. Swazey, president; E. D. Hewings, treasurer, and Douglas A. Brooks, general manager.

SANDERSON & PORTER, contractors for the Meriden & Compounce Electric Railroad Company, have let the contract for furnishing several bridges and buildings on the line of this road to the Berlin Iron Bridge Company, of East Berlin, Conn. The work consists of seven spans of bridges, varying in length from 10 feet to 65 feet, a car barn 50 feet wide and 100 feet long and a power house 45 feet wide and 75 feet long. The bridges are of steel and the buildings have steel framework, brick side

walls and fireproof roofs. The roof of the power house is covered with corrugated iron and lined with the Berlin Iron Bridge Company's patent anti-condensation roof lining. This lining has shown itself efficient in preventing condensation and moisture from the under side of covering and doing away with the danger and annoyance of water dripping on the expensive and delicate machinery below.

WESTERN NOTES

WESTERVILLE, OHIO. The Westerville Electric Company has been incorporated by E. S. Aldrich, 11 Wesley Block, Columbus, O., and H. L. Bennet & Co., for the purpose of lighting that place. A contract has been secured for five years for 10 arc and 50 32 c. p. incandescent lights. The plant will be built at once, and Mr. Aldrich will be manager and engineer in charge of constructing plant. He wishes prices on a 40-kilowatt 220-volt generator, 10 220-volt arc lamps, 6,000 pounds w. p. wire and all supplies required to build plant.

THE WESTERN ELECTRICAL SUPPLY CO., of St. Louis, Mo., report very large sales for the "Loricated" Iron Armored Conduit, for which they are agents, and predict for it very large sales in their territory this fall. A visit to their offices would seem to indicate that prosperity is indeed with them, as their large force of employees seem to be rushed with work in their various departments, and the management report that business this fall has more than exceeded their expectations; and they inform us that business seems to be most active in all of the five departments into which their business is divided. They have just issued a 753 page cloth bound catalogue, illustrating the general lines of electrical merchandise that they handle, but it seems they are now issuing books for their various departments in addition to this general catalogue, and we understand that their catalogue No. 16B, devoted entirely to electrical railway material, is now ready for distribution.

NEW YORK NOTES

GOLDMARK & WALLACE, 121 Worth street, New York, have recently received several large orders for Koch dynamo brushes. The fall season with them bids fair to be a large one.

ADVERTISERS' HINTS

THE BABCOCK & WILCOX CO., 29 Cortlandt street, New York, present some very interesting details regarding the selection of material used in the construction of their boilers. They also include a partial list of street railway companies for whom they have installed boilers. They state that nearly 2,000,000 h. p. have been sold by them and their output is nearly 300,000 h. p. per year.

THOMAS A. EDISON, Jr., 27 William street, New York, says that no central station manager who consults his own and his patrons' interests will fail to use the "Edison, Jr." incandescent lamps. Several of their features are mentioned.

THE FOREST CITY ELECTRIC CO., Cleveland, Ohio, advertise drop-forged and roll drop commutator bars for railway and special uses in all styles and sizes made true to gauge of pure Lake copper. They also advertise the protected rail-bond designed to be placed under the first plate. They say it is flexible to vibration and yielding to expansion and contraction; has solid copper terminals, cast welded onto copper wires and no solder. They furnish screw welders for fastening the bond to rail, and will send samples and catalogues on application.

THE MOLONEY ELECTRIC CO., 6 North Twelfth street, St. Louis, Mo., advertise transformers which are fully described on another page of this issue.

THE C & C ELECTRIC CO., 143 Liberty street, New York, are building slow-speed multipolar generators in sizes ranging

from 20 kilowatts to 200 kilowatts for belting or direct connection. Their substantial construction, correct design, and their ability to stand severe overloads without objectionable heating or sparking make them specially desirable for railway and power service.

F. E. HOMER & CO., Bush Building, Cleveland, Ohio, build, refill and repair commutators for motor generators and special work. They guarantee their work satisfactory.

JULIUS ANDRAE & SONS CO., Milwaukee, Wis., state that the "Andrae-Ericsson" telephone is made to receive sounds clear, sharp and strong, that exchanges equipped with them give perfect satisfaction.

THE CLEVELAND ELECTRIC TRADING CO., Cuyahoga Building, Cleveland, O., are out for business and want to sell, buy or exchange any old thing in the way of electrical apparatus.

THE ELECTRIC STORAGE BATTERY CO., Drexel Building, Philadelphia, advocate the use of the storage battery for trolley regulation. A very convincing testimonial as to their efficiency in this work from the Easton, Pa., Edison Co. may be found in their "ad" this week.

THE C. W. HUNT CO., Water street, Staten Island, N. Y., illustrate a large coal conveying plant they have just installed for the Calumet and Hecla Mining Co. at Linden, Mich. They note some of the features of this installation and have a word to say about their Manila rope transmission system.

THE GOLD STREET CAR HEATING CO., Frankfort and Cliff streets, New York, recommend their system of heating where the greatest amount of heat and a uniform distribution of the same is required at the least expenditure of current.

The Electrical Engineer.

Vol. XXVI.

SEPTEMBER 15, 1898.

No. 541.

THE CROSS-COUNTRY ROADS AT CLEVELAND, OHIO.—II.

BY C. B. FAIRCHILD.

The Akron, Bedford & Cleveland Railroad Company.

Mr. Will Christy.

THIS was the second of the cross-country lines to be constructed, and had its inception in the fertile brain of Mr. Will Christy, who was mentioned in connection with the development of the Cleveland & Berea line, he having been prominently identified with the Akron, Bedford & Cleveland Railroad Company since its origin. The line, which was opened in 1895, extends in a southeasterly direction from Cleveland through a prosperous farming country, with houses at short intervals all along the route, owned by wealthy farmers, who are liberal patrons of the line.

The route is through a rolling country, some of the grades being quite abrupt, and the road dives in and out of narrow valleys with an ever-changing landscape view. While there is frequent change in grade, none of the hills is very steep until the suburbs of Akron are reached, when the road makes an abrupt turn around the edge of a steep cliff along the cañon of the Cuyahoga River, where it descends rather abruptly, crosses a steel truss

CUYAHOGA FALLS POWER STATION, A. B. & C. R. R.

bridge over the cañon, and after a sharp rise descends to the city over a precipitous grade 1,100 feet in length, with an average grade of $11\frac{1}{2}$ per cent., but with a maximum of 13 per cent., near the crown of the hill. The region about the Cuyahoga Cañon is very wild, and the glens provide many attractive features for pleasure-seekers. The glen is about as Nature made it,

but the company is undertaking improvements in the way of laying out walks and providing shelter. Besides the scenery of the Cuyahoga River to make this neighborhood attractive is the region about Silver Lake, less than a mile distant, which has also been fitted up as a pleasure resort. To this lake a branch road has been built, and during the summer season A. B. & C. excursion trains are run direct to the grounds.

The main line passes through the villages of Bedford and Cuyahoga Falls to Akron, which is a progressive manufacturing city, having, with its suburbs, a population of about 40,000. The city is noted for its numerous potteries, in which clay products of almost every description are manufactured, some of the largest works being devoted to the manufacture of sewer pipe, vitrified clay conduits for electric wires and porcelain insulation. There is also a very large establishment engaged in the manu-

DIAGRAM SHOWING USE OF PORTER DERAILING SWITCH ON A. B. & C. R. R.

facture of rubber goods, including hard rubber for insulating purposes, known as the B. F. Goodrich Company, and one in the manufacture of electrical supplies. The farm and dairy products of the region furnish considerable business for the road, this being especially true of the milk trade. The line throughout its entire length has many attractive features for pleasure seekers, and notwithstanding it parallels two steam lines which operate between Cleveland and Akron, it enjoys a very liberal patronage, which is constantly increasing because of the new homes that are being erected along the line of the road. Many city people have been induced to leave the city for a country life "where they can have the skies and woods for friends."

The total distance from Square to Square in the two cities is thirty-six miles, and the cars are run on a half-hour headway, requiring two hours and ten minutes to make the trip. The schedule speed, outside of the cities, is twenty-five miles per hour, but on the level sections and on long down grades the speed frequently reaches forty and even fifty miles per hour. The fare for the round trip, including a transfer in each city, is \$1; for one way, 60 cents.

ROADBED AND OVERHEAD CONSTRUCTION.

The tracks are laid along one side of the highway, the roadbed being slightly turnpiked to provide for drainage. The more recently constructed portions of the track are of 70-pound tee rail, heavily bonded with a large contact, laid on large ties 6x9 inches by 8 feet, and spaced two feet centres, this being the adopted standard. Turnouts, with suitable spring switches, are provided at such intervals as allow for a half-hour headway. From Cuyahoga Falls to Akron the road is double tracked. Telephone boxes at each of the turnouts enable conductors to communicate with the superintendent and receive orders. Formerly they were required to report at each turnout and receive orders, but now, if on schedule time, the conductors report only at the terminals. Derailing switches are provided at steam railway crossings.

These switches, of the Porter type, are manufactured by The Cleveland Frog & Crossing Company, of Cleveland. In normal position the switch is open, leading into blind tracks, and before the car can pass it is necessary for the conductor to go forward, cross the steam track and work the operating lever which is attached to one of the side poles as shown in the illustration. The motion of the lever actuates a second lever near the top of the pole from which a wire leads to a pole opposite the switch, where it is attached to a second lever, to which is connected a wire within the tubular pole and which leads out from the base of the pole to the switch, and by means of which the switch is closed for the passage of the car. The same arrangement is followed at drawbridges, and is so arranged that the lever cannot be operated when the draw is open. In some cases the operating lever is attached to a pole on the near side of the crossing, but usually on the opposite side. The position of the switch tongue and rocker bar are clearly shown in the engravings on this page.

Woden side poles with brackets support the trolley and feed wires, and at suitable intervals large-lettered signs showing stop

PORTER DERAILING SWITCH USED ON A. B. & C. R. R.

numbers or stations are attached to the poles. The stations are about one-sixth of a mile apart. At some of the crossroads and at important stations the company has provided small artistic waiting rooms.

In addition to the steel bridge noted above, over the cañon at the Cuyahoga River, the line crosses another similar structure near Bedford which is 300 feet in length and was built by the company at a cost of \$19,000.

POWER STATIONS.

The power is supplied from two plants, one located near Bedford, the other at Cuyahoga Falls. The former occupies a wooden building on the bank of Tinkers Creek and has a capacity of about 600 h. p., included in two units, the engines being simple and belted to Westinghouse multipolar generators; the latter, a brick building, shown in the accompanying engraving, having about the same capacity and being of the same type as the former. The engines are manufactured by the Edward P. Allis Company. The feed wires of the two stations are coupled and the current at the stations is under a tension of 625 volts. The longest distance to which it is carried is nine miles. The capacity of the stations is said to be ample for the operation of the line, notwithstanding the heavy grades. In this connection it may be noted that some of the parties active in the construction of this line are now engaged in building another extensive cross-country road in the southern part of the State, and for this new line have duplicated the Cuyahoga Falls power station equipment. The main repair shop and car house is of brick and is in connection with the Cuyahoga Falls station, at which point are the offices of the superintendent. The offices of the financial and clerical departments occupy rooms in the Garfield Building, Cleveland.

ROLLING STOCK.

The rolling stock consists of twenty-one double-truck cars, an electric snow plough and a number of flat gravel cars. It re-

TRAINS PASSING AT SILVER LAKE SWITCH, A. B. & C. R. R.

quires ten cars to cover the line with the headway as noted above. The car bodies are of Brill manufacture, mounted on Brill No. 27 trucks, are 41 feet long over all and 8 feet 5 inches wide. They are vestibuled and run one way only, loops being provided at each terminal for turning. The cars are divided by a glass partition into two compartments, the forward and smaller one for smokers. Those designed for freight and express have a freight compartment without seats. The cars are constructed with double floors, with paper lining between for warmth, and are all painted a light medium red. The seats are upholstered in plush, which will, however, be rapidly replaced with rattan, and are the same size as those employed in steam practice. Each car is provided with a toilet closet and tank for ice water.

These cars were formerly equipped with two Westinghouse 50 h. p. motors, but more recently a G. E. four-motor equipment has been adopted, with the intention of hauling trailers as the traffic demands. It is found that the cars with four motors make better speed and climb the grades with greater ease than with the two-motor equipment. This decision was arrived at after experimenting with two, three and four motors.

With the four-motor equipments electric brakes have been sub-

CUYAHOGA FALLS, ON LINE OF A. B. & C. R. R.

stituted for the air brakes formerly used. The history of the air brake equipment on these cars is very interesting. The first eight cars equipped were provided with the Hunt air brakes, with axle-driven compressors, after which several independent motor compressors made by the same company were tried. This equipment was followed by eleven equipments supplied by the Standard Airbrake Company with their geared axle compressors. These were installed in August, 1896, and some of them are still running. A trial was also made with one equipment furnished by the National Airbrake Company, and later a number of cars were equipped with the Christensen type of air brake furnished by the Christensen Engineering Company, of Milwaukee, includ-

ing a trial with both axle and motor-driven compressor, all of which are to be replaced by the electric brakes as fast as the four motors are mounted. The experience with some of these air-brakes was in the main satisfactory at the time, but the electric brakes which were put into service on the Cleveland, Painesville & Eastern Railroad and the Lorain & Cleveland Railway having proved satisfactory, brought about the change on the A., B. & C. Railroad. The use of the air whistle in connection with the air brake is said to be a very desirable feature, and the installation on each car of a small motor compressor with a storage tank to provide for blowing the whistle is contemplated.

It is interesting to note the evolution of the cars, motors and trucks in the experience of this road. At first the electric companies opposed the introduction of eight-wheel cars and objected to furnishing an equipment for speeds above twenty-five miles an hour, so that the management was forced to resort to its own designs and seek such builders and manufacturers as would accede to the new demands. Only one company of car builders at first would undertake to build the long cars, and these were replaced after an experience of eight months; in time, however, builders have been enabled to employ such material and so frame their cars that they are now standing up for the most part very successfully under the excessive strain to which they are subjected. Some few, however, are being rebuilt. This company was the first to employ double-plate wheels in this class of service, following the experience of steam roads.

The Akron, Bedford & Cleveland Railroad Company have constructed a large snow plough, or electric locomotive, which is used for clearing snow from the tracks, for hauling gravel cars and for shifting trains of steam railway coaches over the Silver Lake spur from Cuyahoga Falls. This locomotive is equipped with four motors, each of 50 h. p., and is provided with automatic air brakes of the Christensen type, a motor compressor of 5 h. p. being employed.

TRAFFIC.

The number of passengers carried during 1896 was 461,238; in 1897, 476,803; in 1898, to August 1, 262,898, having gradually increased since the road was opened, varying, however, from month to month, depending upon the weather. The express and freight business is at present in a state of reorganization owing to general withdrawal of old-time companies from the electric railroads. The company makes considerable concession in the rates of fare for picnic parties, and gives much attention to this class of traffic.

OFFICIALS.

The affairs of the company are under the direction of Mr. H. A. Everett, president, who is also prominently identified with three other of these roads. Mr. Everett is well known to the street railway fraternity from his former connection with one of the largest street railway systems of Cleveland, and later on with the street railways in Toronto, Canada, and with one of the systems in Detroit, Mich. Charles W. Mason is vice-president, and Mr. F. S. Borton, secretary. Mr. F. J. J. Sloat, formerly superintendent, has severed his connection with the company and is now engaged in building a new line in the southern part of the State, being succeeded as superintendent by Mr. L. E. Beilstein, who is also superintendent of the Cleveland, Painesville & Eastern Railroad.

The Lorain & Cleveland Railway.

THIS was the last of this group of roads to be constructed, having been opened October, 1897, and naturally it embraces all the essential features that the years of previous experience on the older lines had suggested, and it is built from start to finish with an eye single to efficiency and durability. The route is over a perfectly level region, due west from Cleveland, parallel at a distance of about one-fourth of a mile with the shore line of Lake Erie, and is located throughout the whole extent on a private right of way, the county road being between it and the lake shore. The right of way is from 40 to 60 feet in width and guarded throughout by a wire fence made by the Page Woven Wire Fencing Company, of Adrian, Mich. Like the other lines, it runs through a farming region, but one which is almost entirely devoted to fruit raising, the principal varieties of which are grapes, peaches and berries. The grape product, however, predominates, and much of the way on both sides of the line well kept vineyards extend away almost as far as the eye can

reach. Pretty homes may be seen through the trees, and the blue waters of the lake are in view to the north almost throughout the entire length.

Within the city limits the line extends for seven and one-half miles along Detroit street, one of the prettiest residence streets in the city of Cleveland, the lawns of which are ornamented with shrubbery, shade trees and flowers in a lavish manner. Next come a few truck farms, and at long intervals little patches of woodland, which add variety to the natural attractions. The sur-

POWER HOUSE, LORAIN & CLEVELAND R. R.

face is on an average of from 20 to 30 feet above the level of the lake, or at just enough elevation to give a water view of wide expanse, which is dotted here and there with the lake shipping and the pleasure boats for which these waters are noted.

The traffic for the line is mostly from the terminals, and in good weather it is largely a pleasure traffic, there being numerous parks located along the lake front. One of the largest of these—that known as Avon Beach Park—is owned and operated by the railroad company, and embraces a tract of 65 acres, with a water front of 1,600 feet, having a charming bathing beach. Here the company have erected a large pavilion, laid out walks,

ENGINE AND DYNAMO ROOM, L. & C. R. R.

set shade trees and have already made it a very attractive place.

The line terminates at Lorain, a flourishing city of about 15,000 inhabitants. Near by are located the extensive rolling mills and blast furnaces of the Johnson Company, and here are the extensive coal and ore docks of the Cleveland, Lorain & Wheeling Railway and also the roundhouses and repair shops for the same road. The extensive shipyards of the Cleveland Shipbuilding Company are also located here, in which about 2,000 hands are employed. The harbor is also a rendezvous in winter for a large number of the lake craft, twenty-one ships of one company

having been docked here last winter, the crews of which are usually good patrons of the line.

The distance from city to city is twenty-six and one-half miles, and the headway of the cars is one-half hour, so that it required six cars to cover the line. The fare one way is 45 cents and 80 cents for the round trip. The schedule speed outside the city limits of Cleveland, including stops, is thirty miles an hour. On some of the long, straight sections it is fifty-five miles per hour; on speed tests the cars have been run as high as sixty miles per

BOILER ROOM, LORAIN & CLEVELAND R. R.

hour. One who has never had experience in riding on an electric car at this speed can form no idea of how rapid a pace this is—the sensation is so different from that experienced on steam cars. It is usually highly enjoyable, for no one seems to have any sense of danger, or at least, not as much as many people experience on steam cars running at this speed.

ROADBED AND OVERHEAD CONSTRUCTION.

The soil, which is a light clay, is well turnpiked, and the line is ballasted throughout with gravel, which was brought by rail a distance of seventy miles. The construction and equipment of the roadbed copies in every detail that of the American Society of Civil Engineers standard pattern. The rails weigh 70 pounds per yard and are rolled in 60-foot lengths, being connected at the joints with four-bolt splice bars, with nuts and locks on the inside. The joints are bonded with the Columbia type of bond 7 inches in length and of 250,000 c. m. capacity. These are attached to the under side of the rail between the ties. There are five turnouts, each of which is 1,500 feet in length. This furnishes a good meeting distance, so that the cars usually pass without stopping. Spring frogs and also a combination of spring and throw switches are employed. All are provided with signal and switch lamps and targets, after the manner of steam road practice. All the special work was designed by and supplied from the Cleveland Frog and Switch Company.

A double line of trolley wire is provided throughout, and there is not an overhead switch on the system. The trolley wire section is of the cloverleaf or figure-8 form, No. 000, and the two wires are supported about six inches apart from span wires, which in turn are supported from a double row of wooden poles having cross-arms for carrying the feed wire. The latter embrace \$80,000 worth of copper, and there are six feeders leading out, three in each direction, from the power station, with a capacity of 300,000 c. m. each.

The poles are all braced on the inside by 8-foot timbers, which rest against stubs driven four feet deep by piledrivers. On the curves each pole is strengthened by a truss brace composed of strands of heavy galvanized wire, with a turnbuckle in each one. This insures a perfect adjustment of the trolley wires on the curves. The poles on the tangents are spaced 90 feet apart. At certain intervals on the poles there are signs, which read "Stop No. —." These mark the points at which passengers may be taken up or leave the car.

Not far from the city line the road passes over a long steel truss county bridge, which is 120 feet above the water and spans

the cañon of the Rock River. There are four other extensive trestle bridges which were built by the company and which serve to span the channels of small streams. These are of oak and rest on solid foundations. All the bridges are provided with double guard rails, and on all the short curves a single guard rail is placed. A "Y" is provided at the Lorain terminal for turning the cars, and in Cleveland they loop around the Soldiers' Monument, as noted above.

POWER PLANT.

The current is supplied from a single station, which is located at Avon Beach Park, close to the lake shore, twelve miles from Cleveland city limits and seven and one-half from Lorain. The building is of brick, tasteful in design, with a ground area of 100x100 feet. The roof, in which there is a large area of skylight, is supported by steel truss girders, and the floor is cement, so the building is practically fireproof, there being no wood except in the window casing. Four Stirling water tube boilers of 250 h. p. each generate the steam, and these are equipped with the Murphy automatic stokers and coal-handling apparatus, by which the coal is weighed automatically and fed into the hoppers through closed chutes, so that there is no escape of dust. A steam pressure of 130 pounds is usually carried. Five pair of Fairbank scales located on the boiler room floor indicate the weight of the coal, the hoppers and chutes being operated by levers extending up to the steel storage tanks, which are located a little above the boilers and into which the coal is discharged from the steam cars, which are hauled from a neighboring siding by means of an electric construction car onto the steel structures which support the coal bins. The cheapest kind of slack coal is employed for fuel. The feed water is obtained from the lake through a sunken pipe 1,500 feet in length and 24 inches in diameter, which is protected by a crib. The boilers, condensers and pumps are located in a chamber 22 feet below the level of the engine room, the space having been blasted out from the shale rock. Brick walls and cement flooring protect the whole from moisture and provide ample space, so that every machine is readily accessible.

The condensers are of the Blake marine vertical type, with cylinders 10x22x15 inches, so arranged that either one will work with either engine. All the auxiliary steam pipes are in duplicate and are equipped with the Hawley return system and the Thomas feed water governor. The condensing apparatus is so coupled that the engines can be run condensing or high pressure.

The smokestack is of brick, with a 10-foot flue at the base. The base up to the stone coping, a distance of 40 feet, is octagonal in shape and circular above, being in all 200 feet in height.

SIEMENS & HALSKE GENERATOR, LORAIN & CLEVELAND RAILROAD.

To this the smoke is led from the boilers by means of a sheet steel flue.

The power equipment of the station consists of two cross-compound condensing engines of 550 h. p. each. These are of the Cooper-Corliss type and are manufactured by the C. & G. Cooper Company, Mt. Vernon, O. The two cylinders are 20x48 and 36x48, respectively, and are placed about 20 feet apart, so that the crank-bar of each is connected with either end of the generator shaft. There are two governors, that for the steam

pipe being operated from the low pressure side; the other, an emergency governor, which, when it operates above the danger line, not only cuts off the steam but opens a circuit-breaker on the switchboard. The flywheel is 20 feet in diameter and weighs 60,000 pounds.

The generators are each 400 kilowatts capacity, of a new type, with a special design commutator manufactured by the Siemens & Halske Company, of America, at their Chicago works. In this machine the fields are supported on a spider attached to the pillow block on one side and the armature, which is carried by the shaft spider, is cup-shaped, and the coils revolve outside of the field, which arrangement allows of a comparatively low speed, as the engines run only at 85 revolutions per minute. The equipment so far is operating in a highly satisfactory manner and has been tested up to an overload much above the guaranteed

DOUBLE TRACK GIRDER SPAN OVER L. & C. R. R. TRACKS.

capacity. The engines are provided with an automatic oiling device, so that the oil is filtered and returned in a highly economical manner.

The switchboard is equipped with Siemens & Halske switches and the station is protected by tank and Garton lightning arresters and fuses. The auxiliary equipment of the station consists of an overhead traveling crane of 15 tons capacity, with block-lifts of the Yale & Towne type. The steel girders for the crane were provided by the Cleveland Punch and Shear Works and the structural steel by the Forest City Wire and Iron Company. The station is lighted with natural gas from a near-by well, which is driven to a depth of 835 feet. The company also own a second gas well, from which gas is obtained for lighting purposes. The longest distance to which current is carried is twelve miles.

The power station is operated by five men, who work in two shifts, an engineer and fireman being on duty all the time, with an extra man, whose duty it is to see to getting in the coal, taking out the ashes and general cleaning. He also relieves the chief engineer when it is necessary for the latter to be absent from the engine room for construction or repairs. The same number of men would operate the station with twice the output. There is room provided in the engine room for the installation of an additional 1,000 kilowatt unit and room for additional boiler equipment.

The accompanying tables are copied from the log book of the station, and will be found interesting:

Power house report for week ending July 10, 1898.

POWER HOUSE REPORT.

Day.	Kilowatts. 24 hours.	Coal per 24 hours. lbs.	Coal per K. W. lbs.	Coal per H. P. lbs.
Monday	3,969	20,145	5.0	3.7
Tuesday	3,059	16,050	5.2	3.8
Wednesday	2,814	16,675	5.9	4.4
Thursday	2,842	15,825	5.5	4.1
Friday	2,569	15,910	6.1	4.5
Saturday	3,090	16,705	5.4	4.0
Sunday	2,968	16,430	5.5	4.1
Total	2,1311	117,740	...	...
Average kilowatts per days.....				3.044
Average kilowatts per hour.....				176—
Average coal per kilowatt.....				5.5
Average coal per horse power.....				4.0

CAR HOUSE.

The car house and repair shop, which also contain offices for the superintendent and operating offices, is a handsome brick structure 200x65 feet, and is located at Avon Beach Park beside

the tracks, about 1,000 feet south of the power station. This is the operating centre of the system, and is, as before noted, about twelve and one-half miles from the Cleveland city limits.

The repair shop proper is provided with repair pits, in which are located hydraulic portable lifts for handling the armatures, and there is a very creditable equipment of iron working tools, including radial drills, manufactured by W. F. & John Barnes, of Rockford, Ill., and a shaper manufactured by the Ohio Machine Tool Co., of Canton, O. The power for operating the tools is derived from an electric motor, which is run from the line circuit with suitable resistance coils and a circuit breaker like those described for use on the cars. There are two trolley lifts, one of five tons and the other of one ton capacity. A small fan provides air for blowing the forges and there is a hot water system of heating, in which the fuel is natural gas. A second story over a portion of the building provides for store room and for the woodworking department.

ROLLING STOCK.

The car equipment consists of twelve eight-wheel cars, which are all manufactured by the J. G. Brill Company, of Philadelphia; four of these are of recent purchase, the original equipment of the road having been eight cars. The length of these cars over all is 41 feet 10 inches, with 4-foot vestibules, so that the bodies are about 34 feet inside and 8 feet 6½ inches outside measurement. Smoking compartments have been added to six of the original equipment, and rear vestibules have also been put on. Two of the four new cars have baggage compartments.

These cars were essentially described above in connection with one of the other roads, which purchased cars from the same builder. They are, however, somewhat stronger, and in each post a ¾" steel rod is inserted, which is anchored to the steel sill and also to the deck timbers. The carlins are also somewhat stronger than usually supplied. The floors are double, with suitable lining. The interior finish is of light mahogany, with quartered oak ceilings having border decorations. The deck lights are of slightly chipped glass and are operated in groups of two or three by worm and gear arrangement. The glazing is all of plate glass, one-quarter of an inch in thickness, and the partitions between compartments and between the body and vestibules have large glass panels, it having been observed that passengers favor glass partitions, as it gives them a chance to see forward and backward as they travel, and they can watch the movements of the car men. Mirrors occupy the upper corners of the end panels. The seats are of the Bushnell type, some with arms and some without, and are finished in three different styles. In some cars they are upholstered with leather, in other with rattan and still others with old gold plush.

The exterior is painted in Tuscan red, with gold-leaf letters,

TRACK AND LINE CONSTRUCTION, LORAIN & CLEVELAND RAILROAD.

and the interior of the vestibules and door posts are painted white. Electric heaters of the Consolidated Car Heating Company's manufacture are placed under each seat and in the vestibules. Folding safety gates are provided for the rear platform. In some of the cars the rear dash is composed of steel grating.

There are no closets or water tanks. Every car is provided with a portable telephone, which can be attached to the circuit every quarter of a mile, suitable switches being provided and attached to the side poles. There are also stationary telephones at the terminals and at the sidings.

The incandescent lamps are arranged in groups of four, with bronze ornamental holders. There is also an oil lamp provided at each end. The headlights are of the largest size employed on locomotives in steam practice and consume headlight oil. Two incandescent lamps are placed in the sign case on the front dash. Under the canopy in each vestibule in connection with the switch is placed a circuit-breaker of 500 ampere capacity. This is of General Electric manufacture and of "formal" type. No safety fuses are used on the cars. On the floor of each cab is located a $\frac{1}{2}$ h. p. electric motor compressor, also of the General Electric type, which is designed to provide air pressure for sounding the whistles, which are considered necessary safety adjuncts in the operation of this class of high-speed cars. This is started by an automatic controller, and the storage tank, which is about a foot in diameter and three feet long, is suspended from the hood of the cab. The maximum pressure is 30 pounds, and the automatic controller operates under a range of between 30 and 22 pounds.

The trucks are of the Brill No. 27 type, extra heavy, being about 2,000 pounds heavier than the ordinary make of these trucks. The wheel base is 5 feet 10 inches and the double plate wheels are 33 inches in diameter. The power equipment of each car consists of four motors of General Electric make No. 57 and nominally rated at 50 h. p., but about one-fourth over design to provide for operating the electric brakes with which all the cars are equipped. These brakes also are of the General Electric type.

Electric brakes, it should be understood, do not provide a power for operating the wheel brake, but the retarding effect is secured by means of magnetic discs, which are attached to the axle. The discs are about 20 inches in diameter, and in the case of cars having the four motors the revolving disc is cast in the face of the wheel. The stationary shoe disc is mounted loosely on the axle and is provided with coils, which produce magnetic effect in the face of the disc and cause it to approach to the revolving disc. In the operation of the brakes the current is generated by the motors, which are coupled as generators in the act of braking. A special controller known as the G. E. No. B 8 is provided for operating cars having electric brakes. The retarding effect is not due entirely to the friction between the discs, as in the case of ordinary momentum friction brakes, but is chiefly due to the making and breaking of the magnetic circuit. The frictional wear between the discs is comparatively light.

The disc on the car wheel will always outlast the life of the wheel, while that of the stationary disc shoe can be worn off to the depth of about one-half inch, and in the case of this line, has a life of about eight months, when a new face of soft cast metal $\frac{5}{8}$ " in thickness is bolted on at a cost of a few dollars and saves the renewing of the magnetic disc, which would ordinarily cost about \$33. In casting the renewing plates irregular channels are left in the metal about a half an inch wide, which are filled with babbitt, which is planed off flush with the face of the disc. This provides for lubricating the face of the discs and prevents the metal from being melted by the excessive heat generated in the stopping of these high-speed cars.

This method of braking is in high favor with the officers of the road, as it is claimed to be very economical, the expense for renewal being much less than that required in the renewal of brake shoes with other types of brakes. On commercial tests one of these cars, which weighs ordinarily 40,000 pounds without passengers, can be stopped when running at a 45-mile speed in a distance of 311 feet on a good rail, or in 11 seconds.

The trolley wheels are of ordinary size, but are cast from a special composition of metal, which gives them a life of nearly a week, even at these high speeds. These are provided with an unusually large graphite bushing, the dimensions being $2 \times \frac{5}{8}$ inches.

An electric construction car of the J. G. Brill manufacture, which is equipped with four motors, is utilized for hauling and shifting the coal cars, and in winter by attaching a suitable nose and flange is utilized as a snow plough. The region, however, is not subject to a very heavy fall of snow. Being so near the lake there is but little accumulation.

TRAFFIC.

The number of passengers carried thus far since the opening of the road in October last is 258,000, with a notable increase from month to month. There is also a considerable income from the express and freight traffic, which is controlled by the company's messengers, but which is not yet as extensive as on some of the other lines.

In the construction of the line Mr. C. W. Wason, who is also identified with some of the other lines, acted as consulting engineer for the entire work, Mr. A. P. Ruggles being chief engineer. The power house construction and equipment was entrusted to E. P. Roberts & Co., consulting engineers, with J. N. Richardson as architect, who also designed the car house.

The business and operating affairs of the company are under the management of Mr. B. Mahler, president, to whose efforts chiefly the line had its origin; E. G. Tillotson, vice-president; E. W. Moore, treasurer; J. B. Hoge, secretary, and F. W. Coen, assistant secretary. W. E. Davis, formerly connected with one of the Detroit railway systems, is superintendent.

The Carrying of United States Mail Matter on Interurban and Street Railways.¹

BY W. S. DIMMOCK.

THERE is probably nothing, or one might say, no one thing which is of more importance to the perfection of an absolutely satisfactory mail service than the saving of time; the electric canceling machine and the numerous contrivances of the manufacturers' craft employed in the handling of mail matter, all aim at the one end—economy of time. This is probably the most potent argument in favor of the electric car service for the transmittal of mail matter to and from depots, sub and suburban stations, to the main post offices. As a general proposition the schedule time of the electric cars is absolutely to be depended on; experience has demonstrated that the list of casualties likely to interfere with the progress of a car upon its designated route is smaller than that which often hinders the wagon service. In the case of the Omaha office, where I have had the best opportunity for observation, a noticeable gain is made in the service between Omaha and Council Bluffs, a distance of five miles, and Omaha and South Omaha, of the same distance. Here the advantage is not confined to the saving of time, but in the increased number of dispatches it is possible to make. The frequency and regularity of time on the electric car lines makes it possible to dispatch mail matter from one office to another, or from main office to sub-stations, to the best possible advantage, since the time can be regulated by the dispatching office at will in order to make certain outgoing trips of carriers, whom it might be impossible to reach if the regular running time of the regular mail trains must be considered, or the possibility of using the wagon service.

Before the electric line between Omaha and Council Bluffs undertook to handle the mails between these cities the mails left the main post office by wagon, and were conveyed to the depot of the Union Pacific Railway, which is a distance of one mile in Omaha and 1.8 miles in Council Bluffs, where they were then conveyed by train across the river, a distance of five miles. The Union Pacific at this time had about eleven trains in twenty-four hours, and part of these trains at night, after business hours were over for the day, thereby making the mail service so very unsatisfactory that the public began to clamor for the mail to be carried by the electric railway from the time the road was open. We finally made a contract with the Government to carry the mails between the two cities, and the public discovered at once that we were transporting these same mails from Council Bluffs to Omaha in the same time that it formerly took to deliver the mail by wagon from the Council Bluffs post office to the Council Bluffs depot, thus saving the time consumed by the Union Pacific train between the cities and time consumed by wagon from depot to post office in Omaha. In fact, the mail was probably in the hands of its owners and answered in some cases long before it had crossed the river by the old route. Or a man could mail his letter in Council Bluffs, walk to Omaha and wait for its delivery under the old system, while the new route makes it possible for him

¹Read before the Amer. St. Ry. Assoc. Abstract.

to mail a letter when he goes to his office in the morning and get his answer by noon. No doubt an investigation will prove the same conditions exist in nearly every State in the Union at hundreds of places. This being true, we have shown the value of the service.

Now let us investigate the compensation. After it was discovered that the electric railways could handle the mails with so much satisfaction to all concerned, the managers of the railways thought they saw a great protection during strikes, etc., in the Government, and were ready to carry the mails at most any price, but I believe experience has taught us, through some of the strikes in the East, that they did not find the protection anticipated. The electric railway managers were figuring on the basis of what the Government had done for the steam roads during such troubles, and, while seemingly the comparison was a good one, it was erroneous from the fact that a mail car could be attached to an engine hauling ten or fifteen coaches of passengers, and this one train would perhaps clear up the traffic for hours, while with the electric roads, where the headway is anywhere from two to five minutes in large cities, where strikes are liable to occur, one train carrying the mail, which the Government would protect, would make no more impression upon a congested travel than would one drop of water in the ocean. It can be shown, therefore, that the only benefit received by the companies for carrying the mails on street and interurban railways is the compensation allowed by the Government for the same; hence the railways should work with an end in view to make this compensation enough to justify them in looking upon the carrying of mails as a profitable earning, and one which should receive their careful attention. It is true the Government has made some effort to arrive at the cost of carrying the mails, but in doing so, if you will read the report of the committee to the Postmaster General under date of June 25, 1896, which the Government at Washington will furnish you upon request, and which contains a great deal of valuable information, you will see the report treats mostly upon finding out what expense the railways are put to in handling the mail, and not upon how much the value of the same is to the public. This report makes an allowance of three cents per mile for carrying pouches upon electric trains, while in the same report they state: "The closed pouches upon the street cars should be compared with the Star Service, which it replaces," and in the same breath the Government states: "The Star Route service costs 4.94 cents per mile." Thus they recommend three cents per mile only for the electric service with its increased speed and more prompt and reliable handling, in fact, a superior service in every sense of the word. Following this statement they also say: "It is gratifying to report the improved service will not materially increase the expenditures of the Post Office Department."

Where the regulation wagon service in various cities is costing the Government 15.7 cents per mile traveled they only offer the electric companies 16 cents per mile for a 16-ft. car, and at the same time claim the service should be far superior, and that the car will take care of the natural increase for years to come. Does it not look unreasonable for them to dictate to the railway companies such terms when the service is so much superior to the wagon service? Why, in Council Bluffs they pay more for the wagon service to haul the mails to and from the depot, a distance of 1 8-10 miles, than they pay the steam road for hauling it from Council Bluffs to Omaha. Why? Simply because the steam roads are post roads and compelled to carry the mails as the Government dictates, while in the wagon route they are dealing with an individual, and it is impossible for them to make a contract for any such unreasonable terms.

When the Omaha & Council Bluffs Railway & Bridge Company first closed the contract with the Government for carrying mails between Omaha and Council Bluffs the Government allowed this company one hundred dollars per month, and was satisfied it was getting value received until other electric roads commenced to carry the mails more for protection than revenue. The Government then immediately took advantage of the time and opportunity to make an investigation, of which the report of June, 1896, was the result, which reduced our compensation to fifty dollars for nearly the same service. Had the American Street Railway Association handled this matter in the past, as general managers and passenger agents of steam roads handle their affairs, the result of the Government committee's investigation would have been different.

No doubt the companies spoken of in the committee's report to Postmaster-General Wilson, under date of June 25, 1896, as giving information as to the cost of carrying mails and operating mail cars, have since learned through experience that their estimates were entirely too low, although given in good faith at the time. The Chicago City Railway states that the revenue derived for running mail cars barely pays the expenses. Nearly every manager with whom I have communicated is dissatisfied with the remuneration.

It is not for me to say how much we should receive, but for the members of the association to take up the subject by discussion and work it out. This class of service is in its infancy; it will grow from year to year, and after a while be worth thousands of dollars to us annually, and what we do to-day and what we neglect is laying the foundation for the Government to work upon in the future. Then it behooves us to be on the alert and lay the foundation of the compensation so well that the Government cannot tear it down when the time comes for them to declare the electric railroads to be post roads.

Comparative Earnings and Economy of Operation Between Single and Double Truck Cars for City Use.¹

BY RICHARD McCULLOCH.

BEFORE beginning a discussion of this subject, it would be well to define what is meant by single and double truck cars, as these terms are often very loosely used. In this paper a single truck car will mean one in which the body rests upon a truck, the axles of which are parallel with one another and at all times perpendicular to the centre line of the car. In a double truck car, the body is pivoted upon two independent trucks, each of which swings underneath the body with perfect freedom.

Double trucks for electric cars are of comparatively recent adoption. All of the early electric cars were equipped with single trucks, and in this, horse car and cable car practice was followed. As the single truck was first on the ground, and at present largely has possession of the field, it will be assumed that in this case of the double truck versus the single truck, the double truck is the plaintiff and must submit the weight of the evidence.

Double trucks were first applied to cars in the desire to use longer bodies than has been customary. In the use of a single truck the best practice has been to limit the wheel base to about seven feet, as a greater distance than this would cause the wheels to bind in curves. Assuming that the body of the car is twenty feet long and that the platforms project four feet beyond the body, the end of the platform would overhang the axle ten and one-half feet. This is as great an overhang as is customary, although single truck cars have been built with bodies longer than twenty feet. In this case it is necessary to provide extension springs on the trucks to check the oscillation of the car body. With a very long car body, however, the oscillation is not entirely overcome by this device, and the rocking becomes very disagreeable to passengers and very disastrous to the car and track. Twenty-two feet may be arbitrarily established as the limiting length of the body of a single truck car, and if we wish to use car bodies longer than this, we must adopt some truck which will avoid oscillation and which will pass around curves without undue use of power. The double truck accomplishes this, and it was to enable longer bodies to be used that it first came into use.

The truck which was first used for long street railway cars was an adaptation of that used by the steam railroads. This truck contains four wheels of equal size and is pivoted over the centre. It was soon discovered that for street railway use, this form of truck had two very objectionable features, first, that the floor of the car must be high enough above the rail to allow the wheels to swing freely under the car, and secondly, the motor being geared to one axle of the truck, only fifty per cent. of the weight of the car was available for traction. The latter is a serious objection on roads having grades.

From what has been said it will appear that the single truck is the truck for short cars, and the double truck is the truck for long cars. Therefore, a discussion of the relative merits of

¹Abstract of paper read at the 17th Annual Convention of the Amer. St. Railway Association, at Boston, Mass.

these two types of trucks will involve a discussion as to the relative merits of short and long cars. Also, as it is customary to supply long cars with cross seats and short cars with longitudinal seats, we have instead of the comparatively simple subject of single trucks versus double trucks, which has been assigned to your committee, the more complicated struggle between the short car with single trucks and longitudinal seats, and the long car with double trucks and cross seats.

It will be assumed in the discussion which follows that the road possesses the characteristic city travel, a load curve of which is shown in Fig. 1. It will be noted that two very pro-

TABLE I.
Comparison of the cost of wheels and brake shoes on Double and Single Truck Cars for the year 1907.

	Average No. of Wheels used per car per year.			Cost per car per year.				Total Cost per car per year		Wheel Mileage.	
	30"	32"	34"	Wheels.	Labor in Replacing.	Brake Shoes.	Total.	per 1000 passengers.	per car.	30"	34"

TABLES I. AND II.

nounced peaks occur in this load curve, one in the morning from six to nine and the other in the evening from five to seven. It is at these times that the capacity of everything is tried. While the load curves of all city roads resemble each other, it is evident that local conditions will to a large extent determine the kind of car which the railroad company will operate. Some of these local conditions are: The class of people who constitute the passengers, the location of the road with reference to the established lines of travel, the amount of pleasure travel received by the road, and the keenness of competition with other roads. The last is an important condition, because a road is sometimes forced to adopt certain measures for its protection which it would not adopt under any other consideration. In this discussion we will assume that it is to the interest of the road, even if no immediate competition exists, to use all reasonable endeavors to please its patrons, because this policy will render the road more ready to meet competition when it arises.

The expense of the average city road may be divided up as follows: Maintenance of way and structures, 4 per cent.; maintenance of equipment, 7 per cent.; conducting transportation, 52 per cent.; general expense, 8 per cent.; fixed charges, 29 per cent.

It will be noticed that the item "conducting transportation" is more than one-half of the total. This is largely made up of the wages of conductors and motormen, and is proportional to the number of cars operated. Hence, it follows that if we may by the operation of larger cars cut down the number of cars, this account may be reduced in nearly the same ratio as the size of the car is increased. There are many other reasons why the size of cars has been increased, such as the increased volume of traffic due to the higher speed and enlarged territory of the street railroads, the greater comfort demanded by the traveling public, the increased power available for the operation of cars, etc., but it is probable that the present tendency toward the increased size of car bodies is with a view of operating larger units and fewer of them.

A line operating small cars seating 28 persons on a headway of three and one-half minutes, would give the same service from a standpoint of seating capacity if it operated large cars seating 40 persons on a headway of five minutes. Manifestly, this latter service would be preferable from the railroad standpoint for the reason just given, and the question is, would the service be equally acceptable to the passenger. In this comparison we are assuming that the larger car is the more desirable vehicle in which to ride. Would the pleasure of the ride compensate the passenger for the greater length of time which he

would have to wait? This is a question which must be solved by each manager for his particular road, as its correct solution depends largely upon local conditions over which he has no control. The scrutiny with which a passenger chooses a street car varies with the length of his proposed ride. If the ride is to be short he takes the nearest car without reference to comfort; but if he is to ride a long distance, he will walk past several lines in order to choose that one on which he will have the most pleasant ride. The car question then becomes a more serious one with long roads and with roads catering to a pleasure traffic. It has usually been accepted that on those roads having a purely business traffic, the proper car is the short one operated on short headway. The author, however, is of the opinion that even in this case, the long car, operated upon somewhat longer intervals, would be desirable. It has often been observed that where a line operates two sets of cars, a passenger will allow several cars to pass him in order to patronize that type of car which suits him best. This has been observed even in the busy hours of night and morning, when it would be fair to assume that passengers would be hurried and likely to take the first car which passes.

One of the most serious questions occurring in street railway practice is the problem of how best to take care of the rush of travel which comes morning and evening. With our present methods, there are only two ways of taking care of this travel: the first, by increasing the number of cars or units in service, and the second, by increasing the capacity of each unit. The latter method consists of attaching a trailer to the motor car, and where this is done, it is usual also to increase the number of units in service. On first thought there would seem to be no better method of increasing the capacity of a road than by the use of trail cars. They are easily attached and detached, they are in service only when necessary, and they do not require the assistance of additional train men. An examination of the trailer system, however, will reveal the fact that it possesses serious defects. The trailer is not automobile and requires the services of men and horses to attach it to the cars and to move it between the car sheds and the motor cars. The opening between the motor and the trail car increases the danger of accident both to passengers and conductors. The number of entrances and exits is increased, and this augments the work of the conductor in keeping track of his fares and increases the danger of his missing some of them. If an extra conductor is placed on the trailer to collect fares, a great portion of the gain during the trailer system is lost. The use of trailers throws an additional strain on the motors, as a heavy weight is added to the train which is not available for traction. The trouble is intensified as the load on the trailer increases; it makes the train more unwieldy in handling, and is largely responsible

TABLE III.
Comparison of the power required by Double Truck and Single Truck Cars.

TABLE III.

for the difficulty in starting and stopping quickly and in making schedule time.

To obviate the necessity of using trailers, a large car, equal in seating capacity to the combined capacity of the motor and trail car, may be operated. This system, however, introduces the disadvantage of the operation at all times of the day of a seating capacity needed only during a few hours of the day. It also increases the size and weight of the cars and the average power required to operate them.

In order to compare the relative economies of single and double truck cars, their advantages and disadvantages will be

discussed with reference to the following points: Wear and tear on trucks, wear and tear on motors, power required, wear and tear on track, the use of trailers, the seating arrangements and convenience of exit and entrance, the preferences of passengers. These relations will as far as possible be reduced to a money basis, and in order to do so a comparison will be instituted between a road which operates double truck cars and one operating single truck cars, using trailers 26 per cent. of the time to take care of the heavy night and morning travel.

Wear and Tear on Trucks.—It is evident that since a car equipped with double trucks has eight wheels and one equipped with single trucks has four, the former will be the more expensive to supply with wheels. Table I. shows the comparative replacement and cost of wheels and brake shoes on the two roads for one year. Table II. shows the comparative cost of maintenance and repairs of trucks and motors for two years. It will be noted that while the cost per car is much greater on the road using double trucks, the cost per passenger is always the same. It would not be fair to assume from these figures that the cost of maintenance of trucks and motors per passenger is almost the same, no matter what sort of truck is used, because these figures result largely from the fact that in this particular case the double truck car carries the greater number of passengers, but an inspection of the table will emphasize the advantage of the large unit as compared with the small one. It will be seen by a reference to Table I. that the greater part of the increased expense of maintaining the double trucks is due to the renewals of wheels and brake shoes.

In examining the relative strength of the various parts of trucks, the side pieces may be compared to a beam supported at two points and carrying a concentrated load. The deflection of such a beam is proportional to the third power of the span; and in the analogy, the span corresponds to the wheel base of the truck. Therefore, the shorter the wheel base, the stiffer the truck side, and in view of its long wheel bases, it is evident that the single truck is at a disadvantage in this respect. For instance, a truck side where the wheel base is four feet and six inches, is 3.76 times stiffer than a truck side of equal section where the wheel base is seven feet.

Wear and Tear on Motors.—Table II., to which reference has already been made, gives the comparative expense of inspecting, repairing and maintaining the motors of double and single truck cars. As in the case of the trucks, it will be noted that while the expense per car is much greater in the case of the double truck car, the expense per passenger is nearly the same.

Table IV. gives the relative weights carried by the different cars, when empty, seats full, and car crowded. It will be noted

and the cost of maintenance are roughly proportional to the number of passengers carried with either style of truck.

Wear and Tear on Track.—The wear of the rails of a street railway track is due to the grinding action of the wheel on the rail, and this is proportional to the weight on the wheel, but is intensified by the dirt on the rail, which causes the wheel to slip and acts as an abrasive agent after the slipping has begun. The weak point of a street railway track, however, consists of the joints and the openings in the special work. The energy

FIG. 1.

of the blow which the wheel strikes as it passes a low joint or a crossing is equal to the product of the weight of the wheel and the height of the drop. Therefore, on any given track both the wearing action of the wheel and the destructive action of the wheels are proportioned to the weight which rests upon it. If the number of wheels under a car be increased, the number of blows which a low joint receives is also increased, but the intensity of each blow is diminished. Double trucks are at no disadvantage as compared with single trucks in this respect, unless the weight of the car be increased. Due to the shorter wheel base, double trucks go around sharper curves, and go around the same curve with less output of power and less wear on the rail than single trucks. The double truck fell into disrepute when the maximum traction truck was first exploited on account of its liability to leave the track. This was due to the small amount of weight which was placed on the small wheels. It is now customary to place thirty per cent. of the weight on the small wheels, and with track in fairly good condition, no difficulty is encountered in keeping cars on the track.

The Use of Trailers.—In the case of the two roads under discussion, the road operating single truck cars attaches trail cars to the motor car for two trips in the morning and two trips in the afternoon. For the entire year, trailers were operated on 26 per cent. of the trips. Allusion has already been made to the use of trailers. The advantage of the trailer on this particular road arises from the fact that the load peaks are unusually sharp. The use of the trailer increases the capacity of each unit during the heavy hours of morning and evening travel and during rush travel due to baseball games and races. On this particular road the motormen and conductors are paid ten cents per trip extra for all trips where a trailer is attached to the motor car. This expense largely offsets the value of this arrangement. There is no question but that the use of the trail car increases the number of accidents for two reasons; first, because the trailer is another car, and second, because the opening between the motor and trail car is a dangerous one for a passenger boarding or alighting from the car. It is impossible to estimate the money value of this accident liability, because in the case of many accidents it is difficult to determine what proportion of the damage was due to the trailer. Trailers must be switched at the ends of the roads and at the car sheds, and require men and horses for this purpose. The use of trailers also entails other expenses, such as car heating, cleaning, repairing and car license, which should be charged against the trail car system. To counterbalance all these disadvantages, the only advantage which the trail car system possesses is its flexibility.

The Seating Arrangement, Exit and Entrances.—As has already been stated, the cross-seat is used almost so universally in connection with the double truck car, that it is fair to consider the economy and efficiency of cross-seats and longitudinal seats in connection with the discussion. There is no doubt

TABLE IV.
Comparison of weights carried by Single and Double Truck Cars.

	No. of Seats.	Total seating capacity.	Weight empty.	Percentage of weight on driving wheels.			Pounds weight per seat.					
				Car empty.	Seats full.	Car crowded.	Car empty.	Seats full.	Car crowded.	Car empty.	Seats full.	Car crowded.
Single Truck Motor Car.	36	80	10000	100	100	100	278	278	278	300	248	330
Single Truck Motor Car with open trailer.	68	140	21000	76	67	67	284	314	314	360	310	360
Single Truck Motor Car with closed trailer.	48	128	21000	76	72	71	284	293	293	360	318	306
Double Truck Car.	36	110	22600	70	70	70	286	324	324	314	360	344

* Note.—Each passenger is estimated at 150 lbs.

TABLE IV.

that while the percentage of weight available for traction in the case of the maximum traction truck remains constant, in the case of the motor and trailer it falls off as the number of passengers increases, and is especially small if the trailer is proportionately more heavily loaded than the motor car.

Power Required.—Table III. gives the power required to operate the different cars, and is the average of a long series of wattmeter tests. In making these tests, the wattmeter was placed on a car in actual service and allowed to remain throughout the entire day. An examination of the tables will reveal the fact that the power required for the propulsion of the car and the care and repairs which the motors demand are much greater in the case of the double truck car. But if the number of passengers be taken into account, it is seen that the power

that the cross-seat is preferable from the passenger's standpoint, and the reasons for this preference are not difficult to analyze. Passengers often travel in pairs, and the cross-seat gives a privacy to their conversation which is not possible with the longitudinal seat, the jerks due to the stopping and starting of the car are less disturbing to the passenger when he is seated facing the direction of motion, and the cross-seat renders it easier to look out of the windows.

If two car bodies of the same size are taken and cross-seats installed in one and longitudinal seats in the other, the car body equipped with the cross-seats will have the narrower aisle. This induces two disadvantages in the cross-seat car, one, that the crowded capacity of the car is less, and the other, that when the car is crowded, the time consumed in loading and unloading, is increased. The latter difficulty will be the more serious, the shorter the haul and the greater the number of stops.

In the early days of the double truck car, it was customary to mount the body high enough so that the wheels would swing under it. This gave the car a very unsightly appearance and made it difficult of access. Three steps were necessary to reach the platform, and as these steps were steep, this form of car was particularly objectionable to ladies. By the use of the maximum traction truck with 38-inch wheels, however, it is possible to lower the floor to within 37 inches of the rail. By dropping the platform 8 inches below the floor of the car, it is possible to reach the platform by the use of a single step 14 inches above the rail. This renders the car as easy of access as the single truck car. In the opinion of the writer, the fact that the car floor may be so low in double truck cars, is the chief advantage of the maximum traction truck.

It has been attempted to facilitate the loading and unloading of large cars by providing exits and entrances other than the rear door. This practice, however, brings about what is perhaps a more serious disadvantage as it gives the conductor more than one door to watch, renders it difficult for him to keep track of his fares, and increases the liability of his starting the car before a passenger is on or off.

The Preference of Passengers.—The preference of passengers to which allusion has already been made, is undoubtedly in favor of the double truck car. In cities where the entire street railroad system is controlled by one company, this point may not be considered of value, because passengers are obliged to ride in whatever conveyance the company chooses to furnish. However, the experience of roads which have changed their rolling stock from small, single truck cars to large, comfortable double truck cars, is that the travel has shown an immediate increase. Part of this increase has been drawn from parallel roads, but part has been a created traffic. As the accommodations increase, more people ride, and the regular patrons ride oftener. The street car ride, instead of being regarded as a necessary evil, comes to be looked upon as a pleasant part of the shopping expedition, the visit, or the picnic. How great this created traffic will be depends upon the class of patrons served by the road and upon the terminal facilities of the line. The extremes of society, the very rich and the very poor, are not good riders, and it is probable that a road serving either of these classes entirely would get very little return for additional accommodations. The greatest increase would come from those who are now the best patrons of the street railroads, the fairly well-to-do middle class.

In a general way it may be stated that the single truck car is more suitable for short hauls, dense traffic, many stops and low speed. On the other hand, the double truck car is more suitable for long hauls, high speed, few stops, and pleasure travel. In the existence of either extreme condition, it would not be difficult to decide which car to use. It is in dealing with intermediate conditions that the manager must use his judgment.

DISCUSSION.

In the discussion which followed the reading of the paper, Mr. McCormack, of Brooklyn, stated that on their heavy lines they have had between three and four hundred double truck cars and in not a single instance have they been able to lengthen out the headway. The double truck cars increase the patronage to such an extent that they have had to shorten the headway. When it comes down to standing loads and moving crowds, as on Labor Day, he noticed on the cars seating 40 passengers going to Coney Island that the average was 65 on the register.

With a double truck car, and a seating capacity of 60, it is nothing unusual to see 128 or 130 on the register. There are 178 double truck cars running in the service on one line and one can imagine what the travel is on that line. The headway on the Court street line running from New York direct to Coney Island is less than a minute. On the Third avenue line it is three minutes nearly all day, and part of the time two minutes. The headway from Sixty-fifth street to Coney Island, where all the Coney Island cars converge, it is about twenty seconds.

Mr. John I. Beggs, Milwaukee: In the city of Milwaukee we have for three years been experimenting practically with the advantages and disadvantages of single and double truck cars. In 1896 there were put on the system 20 double truck cars with maximum traction trucks. These cars were equipped with 18 double seats seating 36 persons. A year ago, the early part of 1897, in view of our experience of a year in the use of the cars, we enlarged somewhat upon them, improved the trucks to some extent, we thought, by abandoning the maximum traction truck and so building the frame of the car as to in that way obviate what had been with us a very serious difficulty, namely, the forward wheels leaving the rail. We use 30-inch wheels to accomplish it.

Of course the question as to the use of the double truck car is determined by local conditions. Our double truck cars, for the climate of Milwaukee, are to a great extent a necessity. Because of the large open spaces and our short summer season, it is almost impracticable to maintain the duplicate equipment necessary for summer and winter service. I do not know any one now in the service of the company who has not been converted to the use of the double truck car, and we have arrived at a standard. We use a 33-inch wheel in our present equipment we are having built and still maintain only a distance of 32 inches from the rail to the bottom of the sill, and that was one of the difficulties we had to overcome. We are so thoroughly convinced as to the advantages of the double truck car that we are gradually permitting all our single truck cars to be worn out and scrapped as their life is brought to an end.

We have found that the use of the double truck cars has greatly increased the traffic; in other words, the people would wait for double truck cars on certain lines. We brought our average up within two years certainly a mile an hour. Our average speed now is somewhat in excess of 9 miles per hour. We would not be able to do that with a single truck car, because of the oscillating motion and the liability of the pitching to displace the trolley wheel, whereas with the double truck cars we seldom have such an experience. As to the matter of wear and tear, we believe the weight of evidence is in favor of the double truck car. We find that our repairs of springs is possibly 75 per cent. less on the double truck cars than on the single truck cars. We have been able to increase our headway on most of the lines on which we have placed the double truck cars.

As to the four motor equipment, I might say that during the present year we have had ten interurban cars constructed, running between Milwaukee and Waukesha Beach and the city of Waukesha, a distance of 26 miles, or slightly in excess. These cars were carefully constructed after complete investigation and the possession of all information we could get from electrical engineers, and based on this, and our own experience and judgment, we have equipped them with four 1,000 motors, geared to make 26 miles per hour, weighted with 40,000 pounds. Our double truck cars are possibly the heaviest in use anywhere in the United States. They weigh about 35,000 pounds. The latest improved truck permits us to use the 33-inch wheel with the same facility as the 30-inch wheel, with no greater height from the rail.

I can only say, so far as we are concerned in the city of Milwaukee, the double truck car has come to stay.

Test of Willard Third-Rail System.

The installation of the Willard third rail system of electric traction upon a two-mile section of the Long Island Railroad will be begun about September 20, to give a practical demonstration of the effectiveness and safety of this device. Railroad managers from all parts of the country will be interested in the tests to be made as soon as it is in operation.

Equipment and Maintenance of Electric Cars¹—I.

BY M. S. HOPKINS.

WHAT is the best electric equipment to purchase and how can it be made to render the best service at the least cost? is the question which daily confronts the street railway manager, and one on which he is constantly seeking advice. There can be no answer which is applicable to all street railways, and no especial merit is claimed for the views set forth other than that they are the result of experience and born of repeated failures and successes.

CAR EQUIPMENT.

No fixed rule can be laid down for the selection of equipment, as climatic conditions, character of traffic, frequency of headway, conditions of roadway, municipal regulations and grades are all elements which determine what the equipment may or should be.

CAR BODIES.

For years car builders have attempted to devise a car body which would be equally durable in both summer and winter, but, judging from the character of equipment now in use on the majority of roads, such a car has not yet been produced. The combination car with movable parts is not satisfactory for winter use, is troublesome, noisy and cold, and is lacking in many of the essential features of the open car for summer service. The open cross seat car of the barge type, with running boards on the side, seems by far the most desirable type of car for Summer service, affording the largest seating capacity and the best facilities for receiving and discharging passengers, which is a great advantage in city service. Considering all features, the box car with side seats, large windows, wide end door to the side of centre, roomy platform and vestibules closed on one side, seems best adapted to the average condition of winter service. While the vestibule type closed on one side is not so convenient for the handling of large crowds, yet the additional safety afforded on double track roads should receive full consideration even at the expense of convenience. In localities where winters are accompanied with snow fall and freezing weather the vestibule affords protection to passengers, and motormen and conductors are able to render very much more efficient service.

The long car body seems to be growing in favor with the railway manager, due to the comparatively small increase in operation, in comparison to increased carrying capacity, and its allowing of the increase of headway or decrease in number of cars run resulting in a large decrease in operating expense per passenger carried.

The purchaser of car bodies should have a clear conception of the details of car construction, and specifications should clearly set forth the essential feature—minor details of interior finish and decoration being left to the manufacturer.

In the construction of box car bodies, the trusses should be as deep as possible, and great care taken to secure a perfectly rigid fastening at the end of the sill, as the slightest deflection throws an undue strain on joints and framing of car body.

Where side sills are plated on outside with steel plates, all season cracks should be thoroughly filled with a thick mixture of lead and oil, and entire surface given a heavy coat of oil paint before plate is put on. It is hardly necessary to say that all joints should be well leaded and protected from moisture. A heavy steel roof rafter in one piece should be put in at every post, and a saving in maintenance will be made by having platform floors of oak or maple. The trolley stand should be mounted on a trussed support, which will distribute the strain to the ends of car as much as possible.

Ash seems to be almost universally used in post and light framing of cars. This is probably due to the difficulty in securing the grade of oak necessary, the lighter weight of the ash and the greater ease with which it is worked. In spite of these difficulties, oak is far preferable, being stronger and more elastic, and will give a far longer life.

CAR TRUCKS.

Under average conditions a 22-ft. closed car or eight reversible seat open-car body should be the limit for a single truck. Although there are single trucks which will carry a longer body fairly well, yet the increase in maintenance will in most cases

warrant the use of double trucks. The local conditions should govern the type of double truck used, the bolster type in most cases being preferable for long cars on high speed, suburban service, while for city service, where heavy grades and quick starts demand maximum traction, and short curves make it necessary for the wheel to turn under sill, the bicycle type must necessarily be used. This type of truck is no longer an experiment, and while they possibly require more careful inspection and adjustment, very efficient service can be secured from trucks of this type.

Trucks should be made up of a small number of parts, cast and malleable pieces should be the lightest consistent with strength. The springs should be so arranged as to prevent oscillation, and give an easy riding car under all conditions from no load to full load, and when the style of truck is of such design as to prevent the use of an under truss, the spring base must be exceptionally long and the end springs so arranged as to relieve the strain on the car sills.

The brake mechanism should be so designed that the strains will be equally distributed on all parts throughout its range of movement. The pins should be of ample size to provide for wear. The slider method of support for brake beam will be found more satisfactory than the loop support. The minimum amount of friction should exist between brake staff and shoe and release springs be as light as possible.

ELECTRICAL EQUIPMENT.

In the selection of the electrical equipment the main point is to secure equipment of ample capacity and proper design for the service required. In a railway motor the mechanical and electrical features which influence its maintenance should receive very careful consideration. The bearings should be large and lubricated by oil from below and cup grease from above, and so designed that the drip from the bearings will fall outside of frame. The armature should be so constructed as to permit the shaft being pushed out without disturbing the commutator and winding.

I am glad to note that the importance of light weight and slow peripheral speed of armature has been recognized in the recent design of railway motors. The inertia or flywheel capacity of the armature should be the smallest possible, consistent with the work required. Engineers differ as to the best method of suspension. From a theoretical standpoint the cradle or side bar suspension has the lead. The dead weight is largely removed from axle, thereby eliminating to some extent the hammer blow on rail-joints, decreasing the wear on axle brasses and securing the better alignment of gears; yet, in practice, the nose suspension is still preferred by the writer, as the car starts more smoothly—the weight of motor on spring supports overcoming the jerk and quiver so common in other methods of support. The specifications for railway motors, as drawn up by leading manufacturers of to-day, amount to practically nothing, and would suggest that the purchaser of motors in his specifications clearly define the rating heat limit and efficiency.

The series parallel controller is in most respects a satisfactory device, the chief objection being the narrow range of speed on running notches. Specifications for resistance should provide that the last two points of resistance be of sufficient capacity to allow of their continued use as running notches, especially where cars are operated in city service.

There are several types of magazine fuse boxes or cut-outs and single cut-outs using a special fuse, which possesses a number of points of merit. Without going into detail, it is the opinion of the writer that under average conditions the standard magnetic blow-out fuse box, using a link fuse, is preferable.

Each car should be equipped with a thoroughly reliable lightning arrester. The points to be noted in selecting this device are as follows: The kicking coil should always be installed; the air gap should be as small as possible; there should be a positive and quick device for interrupting the current after discharge, and one which will not be injured by discharge; there should be a non-inductive resistance in the main circuit which will limit the flow of current and thereby prevent the opening of the circuit breaker at the station when several arresters operate at the same time.

KANSAS CITY, MO. The Board of Park Commissioners proposes to install an electric fountain in the Paseo at Fifteenth street.

[Entered as second-class matter at the New York Post Office, April 3, 1893.]

Vol. XXVI. NEW YORK, SEPTEMBER 15, 1898. No. 541.

Echoes of the Street Railway Convention.

AN industry, the annual gathering of whose representatives serves to bring together close upon 1,200 registered attendants is an event of more than ordinary import. When to this number of people directly interested are added thousands of others attracted by an exhibition of apparatus connected with the industry, it may be claimed that the event is a notable one. Thus every year the electric street railway convention—for the horse as a factor in the street railway business is now an extinct species—gains more and more in importance and continues to absorb much of the brain and energy and capital of the country. The selection of Boston as a place of meeting was a particularly happy one, because it was the first large city in the country to equip its lines electrically, and its magnificent system of electric railroads of to-day, which was placed freely at the disposal of the members and their friends during the convention, attested fully the high perfection to which the art of urban electric railroading has been brought. Although Boston itself had nothing to offer in the way of conduit electric railways, it did have something superb to offer in the way of subways, and those who have not visited Boston since the opening of the latter can form but little idea of the tremendous benefit derived from the increased speed and general comfort afforded by these tunnels. The Boston Elevated Railroad surely deserves the thanks of the citizens of Boston for the magnificent piece of work undertaken for their convenience, and practically without a cent of expense to the city, which is more than reimbursed for its outlay by the railway company. Nantasket Beach, close by, showed what could be done in the way of third-rail construction.

Boston was most worthy of the occasion. The city itself presented so many attractions and the excursions to outlying points organized for the benefit of the members of the Association and their guests were so numerous that every hour was pleasantly occupied. Indeed, we are afraid that Boston has unfortunately set so high a standard of excellence in entertainment that few convention cities will be able to reach it in the future.

As to the papers read, it seems that those bearing on questions of finance or paying qualities of various operating devices and stimulants to travel aroused most interest and discussion. One of the most timely of these was the paper of Mr. Richard McCulloch on the "Comparative Earnings and Economy of Single and Double Truck Cars for City Use." The author pointed out that this question was dependent to a large extent upon the merits of long or short cars. He proceeded, therefore, to discuss the merits of the latter, and reached the conclusion that local conditions must to a large extent determine the kind of car

which the railroad company should operate. Such local conditions are: The class of people who constitute the passengers, the location of the road with reference to the established line of travel, the amount of pleasure travel received by the road and the keenness of competition with other roads. As to the old question of trailers, their utility is still considered doubtful, as the trailer, not being an automobile, requires the services of men on the car and horses at the car barns. There were, however, questions on which the relative merits of the single and double trucks were directly dependent. These were the wear and tear on trucks and motors, the power required and the use of trailers, the seating arrangements and convenience of exit and entrance and the preferences of passengers. These are discussed in detail, and the final conclusion reached is that the single truck car is more suitable for short hauls, dense traffic, many stops and low speed. The double truck car, on the other hand, is more suitable for long hauls, high speed, few stops and pleasure travel. In the discussion which followed Mr. McCormack, of Brooklyn, made the remarkable statement that the double truck cars had increased the patronage of their lines to such an extent that they were compelled to shorten the headway. This was corroborated by Mr. John I. Beggs, of Milwaukee, who stated that every one in the service of the company has now been converted to the use of double truck cars and that they have arrived at a standard. Also, that the people would actually wait for double truck cars on certain lines, and that it was not possible to obtain an average speed of nine miles per hour with a single truck car because of the oscillating motion and the liability of the displacement of the trolley wheel. On the whole, it appears to have been brought out that a double truck car has decided advantages over the single truck car for city traffic, and wherever used it has come to stay.

The grievances of the electric railroad companies who have contracted to carry mail for the United States Government were ably voiced by Mr. W. S. Dimmock. With the unquestioned and admitted advantages secured to the Government by the trolley postal car, there is every reason for the street railway companies insisting on a fair and just compensation. Take the case of Boston, as mentioned by Mr. Sergeant, whose lines transported mail over 170,000 miles during the first few months of 1898, and to the amount of 100,000 pieces of mail matter a day, but the service only paid its running expenses. Mr. Beggs believed that there was very little profit in the mail service business for street railway companies, claiming that platforms were more advantageous for the accommodation of passengers than for the storage of mail pouches. We are glad to note that an efficient committee was appointed by the Association to look into this matter, and expect to see it accomplish good results.

Another interesting and timely topic on which a paper was presented by Mr. Walton H. Holmes, and which was ably and profitably discussed, was "To What Extent Street Railways Should Engage in Amusement Business." The consensus of opinion appears to be that this question is largely dependent on local conditions, such as the extent of area and population of cities, the climates, the tastes of the people and the nature of the surrounding country. In most cases it appears as if the companies have seen fit to charge a fare in excess of 5 cents to transport people to places of amusement established and kept up by the railway companies themselves. In addition to this, an entrance fee to the place of amusement is generally charged, and an extra fee for any special attraction within the garden itself. This latter was found to be expedient to ensure a profit to the company, if the places of amusement are owned and controlled by city authorities. It appeared to be the general belief that the promotion of amusement enterprises was a good method of stimulating business and that, while it might cause a congestion on a certain part of the line, this portion might serve as a feeder to the others. There was one point brought out in the discussion which was perhaps lost sight of by most speakers, or perhaps has fortunately not been brought to their attention, and that is the liability to accidents where so large a number of persons have to be transported to one place in a short period of time and the consequent loss to the company in the form of payment for damages. One of the speakers had two such cases to deal with recently, and is of the opinion that they have cut a great gash in the profit column of the amusement business. Summing up the matter, however, it appears as if the question is favorably looked upon by street railway managers, and that if properly handled large profits may accrue from this sort of service.

The paper by Mr. M. S. Hopkins on the "Equipment and

Maintenance of Electric Cars" showed that this question is one which requires a great deal of experience in order to be able to determine the best method of taking care of the equipment and ordering the best material for every branch of the service. He does not advocate the trip inspection of cars, as it involves unnecessary expense, requiring, as it does, the services of an inspector, who is necessarily a man of some ability, for each line of cars. Neither does he favor night inspection. The author does not believe in elaborate systems for the periodical testing of insulation, claiming that their value has not been fully demonstrated.

The question of inspection and testing of motors was ably treated by Mr. Fred B. Perkins, who has given this subject careful attention. In his opinion five men are required to attend to the inspection and care of twenty cars, two to do the greasing and inspection of motors, one to keep the controllers in repair, one to take care of the trolleys and assist in taking care of trucks and car bodies and one to have charge of the latter two.

A very exhaustive and helpful paper was that on the "Cost of Electric Power for Street Railways at the Switchboards, Both Steam and Water Power," by Mr. R. W. Conant, of Boston, who has made a careful study of the conditions present in forty-four power stations located at important street railway centres throughout the country. The aggregate capacity of these stations is 98,387 kilowatts, or 131,800 electrical h. p. He brought out the important point that the cost at the switchboard is now to be reckoned in kilowatt hours as the unit of power instead of horse power, which has hitherto been used.

The figures given by Mr. Conant in reckoning the cost of power and the fixed charges in central stations, as well as the method adopted by him for getting at the results, are of great value and importance and by far the most valuable which have come to our notice. They will certainly prove a great aid to street railway managers in the design, construction and economic maintenance of their power stations.

The Work and Needs of Our Patent Office.

IF it be true, as has been said, that the patent office is the pulse of a nation, then these United States must have been in a very healthy condition during 1897 judging from the report of that office which has just been issued. It teems with interesting figures which show that the inventiveness of this country is on the increase, but that the Patent Office is being managed on so economical a basis as to injure the great mass of inventors clamoring for protection and industries awaiting further development.

In 1897 there were received 45,661 applications for patents, which is a greater number than for any previous year in the history of the office. 23,729 patents were granted, which number was only exceeded in 1885, 1890 and 1891, the highest, 26,292, being reached in the last named year. The cash received was the greatest since the establishment of the office; the money expended, \$1,122,843, however, being exceeded in several years. The receipts over expenditures was \$252,798, and the total balance to the credit of the Patent Office in the treasury of the United States on January 1, 1898, was \$4,971,438. Regardless of this laudable state of affairs, there has been no increase in the force or facilities for doing the work. The consequence of this is, as might be expected, that the work of the office is largely in arrears. The number of applications awaiting action December 28, 1897, was 11,382. Of these, 7,858 were applications which had not been taken up for examination. The first few months of 1898 have added largely to this already stupendous accumulation, and unless relief is given by Congress in providing additional force, the work will fall hopelessly in arrears.

It may be of interest to learn that the number of applications filed in 1897 exceeded by over two thousand the total number of applications filed in the twenty-four years from 1836 to 1860. In proportion to population more patents were issued in 1897 to citizens of Connecticut than to those of any other State, namely, 1 to every 786 inhabitants.

As a matter of comparison, it may be of interest to state

that the number of applications in England during 1897 was 30,958, an increase of 765 over the number applied for in 1896, against 45,661 applications and an increase of 1,679 over 1896 in this country.

In submitting his report, Acting Commissioner A. P. Greeley makes a number of recommendations which if acted upon and passed by Congress, would greatly improve the efficiency of the office and increase its field of usefulness. The Commissioner's suggestions are timely and based upon years of active experience in the service of that branch of our Government, and therefore deserve careful consideration. Among these suggestions are the following worthy of special mention: "The Patent Office should command the highest order of talent, and no such body of men as compose the examining corps of the office can be anywhere else brought together for anything like the salaries here paid them. The corps is unsatisfactory only in numbers and permanence." He commends the classification of patents, such as is practiced by the English Patent Office, and says that no public money is asked for or needed for this purpose. The income of the Patent Office is ample for this and every other need. He urges the enlargement of the library so as to increase the efficiency of the search department, which is also inadequate in numbers.

The number of interferences brought before the chief examiner in 1897 was 815, which is additional work for this official and his four assistants, and the Commissioner is of the opinion that the Patent Office should be relieved of this interference work. It has not the proper machinery for conducting such proceedings. A bill providing for the creation of a court independent of the Patent Office for the trial of these cases is now before Congress and should receive favorable consideration. The British Patent Office publishes, in book form, abridgments of patents relating to the various classes of invention. Nearly every Commissioner of Patents for the past forty years has recognized and urged the necessity for the publication of like abridgments of United States patents. They would be of very great value not only to the examiners in the office and to inventors, but to the general public. He urges further, the printing of a larger edition of the official gazette, the expense of which would be but little more than the cost of paper and press work. These copies, properly distributed to libraries and other public institutions, particularly schools in which mechanic arts are taught, would be of substantial service to the public.

He deplors the condition of the scientific library, which, though perhaps unsurpassed by any similar library in the world, is yet far from complete and satisfactory.

As during the past year a number of the most efficient examiners of the office have resigned, because of inadequacy of salaries paid, the Commissioner hopes for speedy action by Congress to lessen or eliminate such occurrences in the future, by giving the men salaries commensurate with their abilities and duties. He touches further upon the necessity for a patent bar and upon necessary changes in the new patent law and laws regarding trade-marks.

A very interesting, though not quite up-to-date portion of the Commissioner's lengthy report is that dealing with the development of industries through patented inventions and the creation of new ones. He devotes entire chapters to the development of the electric railway, the telephone, copper wire and aluminum industries. He tells us that since 1880, 28,457 patents have been granted relating to electrical matters, which represents an income of just one million dollars to the Patent Office and about one and a half millions to the attorneys. Considering these vast amounts of money spent by inventors and companies for having their ideas and rights protected, it certainly seems reasonable to demand prompt action on the part of Congress for providing sufficient revenue to meet the growing and imperative needs of the Patent Office.

Let our lawmakers remember the words of the Hon. A. P. Greeley, that "it is to the stimulus to invention given by our patent system that the great increase in our exports is largely due, and it is on American invention, as fostered and stimulated by the patent system, that we may confidently depend for ability to maintain the high rates of wages paid to American workmen and yet compete successfully in the markets of the world with nations where the workman receives but a meagre return for his labor."

THE seventeenth annual meeting of the American Street Railway Association was held at the Massachusetts Charitable Mechanics' Association Hall, September 6-9, 1898.

TUESDAY, SEPTEMBER 6.

President Lang called the meeting to order at 11 o'clock and introduced Mayor Josiah Quincy, of Boston, who delivered an address of welcome.

The following were admitted to membership in the Association: Elmira & Horseheads Railroad Company, Elmira, N. Y.; Portchester Traction Company, Portchester, N. Y.; Portland & Yarmouth Electric Railway Company, Portland, Me.; Portsmouth Street Railway Company, Portsmouth, Va.

The President then read his address, an abstract of which follows:

We are to-day, for the seventeenth consecutive year, assembled in furtherance of the objects of our Association, under conditions most favorable to a pleasant and profitable meeting, for we are in the house of our father, the city of our birth. As the presiding officer of the Association and in the name of the street railway men of Boston, I bid you a hearty, sincere and joyous welcome.

As I trace the history of the Association from its inception I am convinced that its founders, in the words of Emerson, "builded better than they knew," for is it not remarkable that they should have chosen a name and set forth in our constitution the objects of the Association so wisely and well that no material change has been required to adapt them to present conditions, which are so radically different from those then prevailing. The constitution then as now says: "The object of this Association shall be the acquisition of experimental, statistical and scientific knowledge relating to the construction, equipment and operation of street railways," etc.

The need for experimental knowledge in connection with a mule goes without saying, and statistical and scientific knowledge, with reference to harness, cars or strap-rails sounds very ancient as compared with engines, boilers, generators, girder rails, vestibuled cars, lightning arresters, ohms, volts, watts, amperes, etc., the familiar subjects of to-day. I do not mean, however, to belittle the value of the investigation, discussion and association of the earlier days, because there are too many veterans present (and I might myself be called one), who can testify to the great benefit derived therefrom. It does seem, however, that the necessity for holding meetings in different cities was greater formerly than now, for in order to know very much about what others had done or were doing we had to go to them, whereas now we can see almost everything in connection with our business in the room below, except the mercurial portion known as the State legislature, common council, tax gatherer and ubiquitous damage lawyer, so called.

The President then gave a brief account of the various meetings of the Association.

"I have thus briefly recounted our movements and spoken of the motives which it has seemed from the best information at hand prompted the Association in selecting its places of meeting, and the value of such selections and other reasons why the Association has grown to its present proportions and standing. Its growth and experiences, like all such organizations, have not been without some severe trials, but, unlike the prodigal son, we have wasted none of our substance in riotous living, but have improved at each successive step, and now reach home, not only the birthplace of the Association, but the home of the electrical industries in a larger sense, perhaps, than any other locality in the world. The people of Boston not only furnish money

with a lavish hand to carry forward the work of developing the subtle power now so useful to us and all mankind, but also much of the brains and energy needed to make its use practical. Of this fact one circumstance will bear witness, and it is that Mr. C. A. Coffin, a Boston man, is still retained at the head of the largest electrical manufacturing corporation in the United States, if not in the world.

"In the growth and development of our Association and the business we represent let us not forget the priceless and unrivaled assistance rendered by the technical press. Without a spokesman, a guardian ever faithful to our interests as they have been, our progress would have been much slower and our pathway exceeding rough. All honor to these devoted publishers and editors.

"Nor must we for a moment forget (if we could) the indefatigable supply man, for he is the noblest Roman of them all. It is his courage, foresight and energy in taking up the new and useful article and pressing it upon our attention that helps to effect economies. We may sometimes be prematurely persuaded, but that is not the fault of the supply man; it is simply one of the arts of his trade necessary for us to learn. But, seriously, without them the meetings of our Association would be materially weakened and lose much of their interest and value. Let us, then, not fail to give them and their exhibits all the attention and examination time will permit.

"I desire to call attention to our fellow-workers and associates, the Accountants' Association, who hold their meetings simultaneously with ours each year, and are even now in session in another part of the building. The whole business of the street railway devolves around the accountant's office, and many of us can attest the value of having efficient persons in charge thereof. It is with the hope of enabling them to make their services more valuable to their respective companies that the Association was formed, hence they should receive every assistance it is possible for us to render. I bespeak for them your cordial co-operation.

"In closing I wish to thank our efficient secretary and the Executive Committee for their cordial aid and support during the year, and to assure the members of the Association of my great appreciation of the honor of being called a year ago to the office of president."

The report on the "Comparative Earnings and Economy of Operation Between Single and Double-Truck Cars for City Use" was then read by Mr. Richard McCulloch, the electrical engineer, Cass Avenue & Citizens' Street Railway Company, St. Louis, Mo.¹

The report of the treasurer was presented, showing a balance on hand of \$3,656.28. The Association has a membership of 161 companies.

It having been suggested that all the members of the Association who were present at the organization of the Association in Boston, in 1882, should rise, the following gentlemen arose: Messrs. W. Worth Bean, St. Joseph, Mich.; George B. Kerper, Dayton, O., and Julius E. Rugg, Boston.

Adjourned.

WEDNESDAY SESSION.

President Lang called the meeting to order at 10:30 a. m., and a paper was read on "Carrying of United States Mail Matter on Street Railways," by Mr. W. S. Dimmock, General Superintendent, Omaha & Council Bluffs Railway and Bridge Company, Council Bluffs, Iowa.²

Mr. Sergeant, Boston, in heartily endorsing all that the

¹For abstract of paper see page 251.

²See page 250.

writer had said, gave some interesting data of his experience in Boston. The trolley mail cars were inaugurated May 1, 1895, and the night service June 3, 1895. In 1898 the car mileage will aggregate 170,000 miles.

There were originally twelve stations, to which have been added one at Charlestown, January 1, 1897, and one at Roxbury Crossing, February 1, this year, on which date also a pouch service was established between Somerville and West Somerville. Connections have always been made with Boston & Albany and Providence depots, and Union station. Sixteen men are constantly employed, eight conductors and eight motormen. Out of about 45,000 trips run (to January 1, 1898), there were 360 failures or irregularities, or about 8-100ths per cent., and that was almost wholly due to the snow and the consequent blockading of teams in the narrowest streets. Seven cars handle 100,000 pieces of mail daily. The system is under the supervision of New England Superintendent of Railway Mail. In other cities the trolley and cable service is under control of the local postmaster. Each car handles nearly five and a quarter million pieces of mail, or a total of 36,561,170 pieces for the seven cars in a single year. Mr. Sergeant also agreed with the writer of the paper about the question of compensation, and thought that something might be done by the Association. He said: "We have never received a compensation here which has more than paid our running expenses. I think that any rate that should be fixed in an arbitrary manner, so much a car mile for carrying the mail, is entirely unfair. It all depends, it seems to me, on the conditions; what service is rendered, what the character of the service is, whether combined with passenger service or whether it is done with independent cars, and what the local conditions of expenses are."

Mr. Beggs, of Milwaukee, spoke of the preliminary stages of establishing a mail service through which his company is going at the present time. He did not appear to be enthusiastic over it, because of the fact that it did not seem to promise a profit and that the amount of protection that the various roads expected when they were established as mail routes, has not been of the advantage to them that they had hoped for. He questioned the advisability of carrying mail pouches on the regular cars of the system, saying that the platforms were too valuable to use to carry a mail pouch at three cents a mile, and it would very greatly inconvenience the patrons of the line, many of whom insist on using the platforms, whether one liked it or not. He further agreed with Mr. Sergeant that a committee of the Association should be appointed to take this question up with the Government for the purpose of having a fair rate of compensation.

Mr. Farson, of Chicago, after expressing views similar to those of the previous speakers, moved that a committee of five be appointed to act under the directions of the Executive Committee and communicate with the different members of the Association and get all the facts before them, keep the Association advised of their proceedings and that they have authority to confer with the Post Office authorities. This motion was seconded by Mr. Beggs, and carried.

Mr. Robert McCulloch, of St. Louis, stated that one of the roads in St. Louis made a contract with the Government to carry the mail and had two cars built especially for the purpose. They expected to derive a benefit by being able to designate the road as a U. S. mail route, and they had the inscription made on their cars, "U. S. Mail." As soon as the cars appeared on the streets, at the suggestion or interference of somebody, no one knows who, the Government required the sign to be taken off all the cars.

Mr. Dimmock, Council Bluffs, pointed out that the committee should keep that point in mind; it is in the power of the Association to dictate terms to the Government.

Mr. Payne, Milwaukee, expressed the belief that the trouble lay largely with Congress.

The Secretary then read the paper on "Maintenance and Equipment of Electric Cars for Street Railways," by Mr. M. S. Hopkins, electrician, Columbus Street Railway Company, Columbus, Ohio.

Mr. Sloan, of Chicago, in discussing the paper, stated that he did not utterly condemn night inspection. With them, he said, night inspection works quite satisfactorily for several reasons; the main one being that motor brushes were changed every

night. It works well on the commutators and results in very little burning down of the commutators, and besides, a car cannot be overhauled too often.

Mr. Hawken, Camden, Me., said that he had noticed that the rear motor on the series point with the fields does about all the work, and the forward motor does very little. He knew of one road in particular that uses this point very largely, and they have a great deal of trouble burning out armatures, and he should like to know which was really the most efficient point in running the motors on series connections.

A vote of thanks was then tendered to Mr. Hopkins.

Mr. Ely extended an invitation to the members of the Association to attend the annual convention of the New York State Street Railway Association, which will be held at the Manhattan Beach Hotel on Tuesday and Wednesday, September 13 and 14.

An adjournment was then taken until 9:30 o'clock Thursday morning.

THURSDAY SESSION.

President Lang called the meeting to order at 10:30 a. m. An invitation was sent to the International Association of Factory Inspectors, which were in session at the House of Representatives, to attend the sessions of the Association and to inspect the exhibits.

The following paper was then read: "To What Extent Should Street Railway Companies Engage in the Amusement Business?" by Walton H. Holmes, General Manager, Metropolitan Street Railway Company, Kansas City, Mo.

Mr. Wyman, New Orleans, in opening the discussion, by request, expressed his positive belief that a strict railroad man should stick very closely to his line of work, and that he had very little freedom or time for going into the amusement business or any other sort of business that was not intimately connected with the daily operation of his cars, the management of his power plant and that style of business and methods that pertain specially and particularly to the working of his road. He said that he had found, however, that in a great number of cities this promoting of amusement enterprises was a very good method of stimulating the business of the company, and that Mr. Holmes was right in saying that it was a proper thing for the street railway companies to aid in the development of the municipal improvements like public parks, etc. Regarding the question of congestion of travel, he stated that they are always willing to have a good deal of congestion in running a street railroad. It is always to be remembered, he said, that if a resort at the end of some particular line should, for the time being, congest the travel upon that line, in a great many instances they used that line as a feeder to the others.

One thing we must always remember, he continued, that is that street railroad riding is, after all, a habit. As a habit it is growing.

Mr. Davis, Williamsport, stated that the experience in Pennsylvania among the small towns, is that the profits derived from the amusement business is not in proportion to the risk of the money spent, and in quite a majority of places, the rule being that it is almost impossible for the manager to separate the hot weather travel on amusement lines from the travel due to the entertainment or park itself.

Mr. Holmes, Kansas City, replied that as far as Kansas City was concerned, where they had the out-of-town parks, they had kept careful record of the business because they sell tickets to the park, and he would be glad to talk that over with anybody or send information.

Mr. Beggs, Milwaukee, stated that from his experience and observation in various cities, he did not believe that it paid a street railway company to go into the amusement business.

Mr. Harrington, of Camden, stated that they were making some money, but whether they would make the installation and furnish the park if they had to do it over again was a question.

Mr. Clafin, of Boston, speaking of the Norumbega Park, said that they had a very different experience from some of the gentlemen who had spoken. They have adopted the practice of charging an admission fee for the park and discriminate in favor of their railway patrons. Their railway carries its patrons a distance of five and a half miles for five cents. They sell on their cars for 15 cents a round trip ticket which includes admission to the park. People going on foot or bicycle are charged ten cents admission. The result is that the railway patrons get admission for five cents and the other people pay

¹See page 255.

ten cents. The result has been that the park has maintained itself and costs the railway company nothing whatever for its maintenance.

President Lang, of Toledo, related a similar experience with a park on the lake shore. In addition to charging fifteen cents for the round trip and admission to the grounds, instead of giving free seats in the main park or body of the house, they put in reserved seats for which they made a charge of ten cents. They found that was working so well that they went into the gallery and put in reserved seats in the first two rows. There are also boxes that seat four persons which sell for twenty-five cents. The company found this last year that they came out a few hundred dollars ahead of the operating expenses, but they ran the casino company as an entirely independent company without any relation to the railroad company at all. It increased the earnings of the railroad companies about \$40,000 last year. This year the casino company will net about \$6,000, counting a fair depreciation upon the buildings, and the railroad company will increase its earnings over \$50,000.

Mr. Wyman, New Orleans, gave some interesting details about a resort on Lake Pontchartrain, about six miles from the city. He said that they keep an accurate record of their operating expenses and receipts, and they find that their proportion of receipts to expenses varies little from the ordinary electric road.

Mr. Thompson, Muskegon, gave some interesting details about a park at Muskegon, and its pavilions and theatrical attractions. He was of the opinion that a good park with good attractions was a paying venture for a street railway company.

Mr. Cahoon, Elmira, spoke of the increased liability to accidents, and believed that the matter of damage suits and of the liability for damages that are incurred incident to the traffic increase should be considered.

Col. Heft, Meriden, believed that the street railway men of today have run mad on the question of amusements, providing everything without any recompense whatever, and if they were going to make these parks pay they must be run upon a business basis and an admission fee should be charged.

Mr. W. Worth Bean, the chairman of the nominating committee, then presented the following ticket, which was unanimously elected:

President, Charles S. Sergeant, second vice-president Boston Elevated Railway Company, Boston; first vice-president, Henry C. Moore, president Trenton Street Railway Company, Trenton, N. J.; second vice-president, Ernest Woodruff, president Atlanta Consolidated Street Railway Company, Atlanta, Ga.; third vice-president, Walton H. Holmes, general manager Kansas City Railway Company, Kansas City, Mo.; secretary and treasurer, Thomas C. Pennington, treasurer Chicago City Railway Company, Chicago, Ill. Executive committee, Albion E. Lang, president Toledo Traction Company, Toledo, O.; George E. Yuille, second vice-president of the West Chicago Street Railroad Company, Chicago, Ill.; Frank Jones, president Memphis Street Railway Company, Memphis, Tenn.; John I. Beggs, general manager Milwaukee Railway and Light Company, Milwaukee, Wis.; Ira McCormick, general superintendent Brooklyn Heights Railway Company, Brooklyn, N. Y. The next place of meeting will be Chicago, Ill.

The president then appointed a committee to look into the matter of the carrying of United States mail matter on street railways.

Mr. T. Y. Dzushi, Chief of Finance and Manager of Stores of the Imperial Government Railways of Japan, and Mr. K. Sugahara, chief engineer of the Kobi and of some street railroads soon to be built in Japan, being called upon, the latter addressed the convention briefly on the electric outlook in Japan.

The secretary announced the names of eight new companies that had joined the Association since the opening of the meeting.

A paper was then read on "Inspection and Testing of Motors and Car Equipments by Street Railway Companies," by Mr. Frederick D. Perkins, electrical engineer Toledo Traction Company, Toledo, O. The paper was accepted with thanks and the meeting adjourned till next day.

FRIDAY SESSION.

The president called the meeting to order at 10:40 a. m. and a paper was read on "Cost of Electric Power for Street Railways at Switchboard, Both Steam and Water," by R. W. Conant,

electrical engineer Boston Elevated Railroad Company, Boston, Mass.

On motion of Mr. Goff, Fall River, the committee on "Standard Rules for Government of Conductors and Motormen" was continued for another year and the sum of \$200 was appropriated for its use.

On motion of Mr. McCormack, of Brooklyn, the thanks of the convention was given to the press of Boston for the intelligent manner in which they had written up the proceedings of the convention. The installation of the newly-elected officers was next proceeded with.

President Sergeant then addressed the convention and made a very happy speech.

On motion the convention adjourned sine die, to meet in Chicago in 1899.

Convention Notes.

THE entertainment provided for the attendants at the convention surpassed in scope and lavishness anything that has thus far, we believe, been attempted in connection with any of the electrical conventions, and, what is more, the manner in which the programme was carried out was worthy of all admiration. As a matter of fact, there was something to do or see from the beginning to the end of the convention.

On Tuesday afternoon a special train took a party of several hundred to Lexington, where a visit was paid to the Battle monument, and a short account of the memorable skirmish was given by the Rev. Mr. Staples, secretary of the Local Historical Society. A visit was also paid to the house in which Hancock and Adams stayed on the night preceding the battle.

Boarding the train again, the party was taken to Concord, and, entering 'busses in waiting, started on a tour, taking in all the points of historic interest in that beautiful old town. Among the points visited were the old Wright tavern, the homes of Emerson and Hawthorne and of Mr. Bull, originator of the Concord grape. The battleground and the statue of the "Minute Man" at the bridge were also visited, as well as a number of other places of historical interest, and the tour was concluded by an all too short stop at the house of the local historical society, where many of the most interesting relics of the Revolutionary period were inspected.

It might have been supposed that this would have been enough for one day's pleasure, but not so. In the evening a reception was held at Revere Hall, with dancing, and a sumptuous collation was served later.

On Wednesday morning the ladies were taken to points of local and historical interest, being accompanied by a guide.

At 2 o'clock on Wednesday afternoon the members took the special cars placed at their disposal by the Boston Elevated Railroad Company from the Brunswick to the wharf, and boarded the boat for Nantasket Beach, passing through the beautiful harbor. The various beach attractions, including the chutes, served to while away the afternoon. Quite a large party, at the invitation of Col. Heft, boarded a special train on the Nantasket Beach Road, operated on the third-rail plan, and were taken quite a distance, inspecting the power house on the way. At 6 o'clock the members sat down to a clambake at the Ocean View House, and it was nearly 10 o'clock before the party were landed at their destination in Boston, special cars awaiting them at the wharf to take them back to their headquarters at the Brunswick.

On Thursday morning the officers of the Association, accompanied by the ladies, were driven on tally-ho coaches through the parks and through several of the finest residence streets of Boston, including Beacon street and Commonwealth avenue.

The convention adjourned somewhat earlier in order to prepare for the afternoon trip to Plymouth. Arrived there, special cars and coaches conveyed the party to the National Monument, commemorating the landing of the Pilgrims, and from there the party were driven to the celebrated Plymouth Rock, now housed under a beautiful canopy of granite, and many took the opportunity of stepping on this historical stone. After a drive about the town and the inspection of other landmarks, the party proceeded to Pilgrim Hall and viewed many of the historic relics of the "Mayflower" and its passengers. Refreshments were then served at the Samoset House, and toward 5 o'clock the party boarded the train for Boston.

In the evening the annual banquet of the Association was held at the Brunswick. The retiring president, Mr. Albion E. Lang, presided, with the incoming president, Mr. C. S. Sergeant, seated

at his right. The invited guests included Governor Wolcott, of Massachusetts; Mayor Quincy, of Boston; Mr. George G. Crocker, chairman of the Rapid Transit Commission, and a number of others. The after-dinner toasts on the menu were as follows: "Commonwealth," Governor Wolcott; "The City of Boston," Mayor Josiah Quincy; "Rapid Transit in Boston," Mr. George G. Crocker; "The New England Bar," Mr. Samuel J. Elder; "Orators and Oratory," Mr. Collins; "The New England Press," Mr. Stephen O'Meara, of the Boston "Journal." Governor Wolcott was unable to attend, but was represented by his private secretary, Mr. J. M. Perkins. Mr. Collins was also unable to be present. President Lang also called on Brig. Gen. W. A. Banker, first vice-president and general manager of the Boston Elevated Railway Company. Mr. Sergeant, the president-elect, being called upon by the president, made a few remarks expressing his thanks to the Association, and after a word of farewell by Mr. Albion E. Lang the banquet came to an end with the singing of "America."

On Friday morning the ladies were taken on a shopping trip, visiting the principal stores, and in the afternoon the members were taken on an excursion to Norumbega Park.

The exhibition, held at the Mechanics' Building, on Huntington avenue, was most representative of the art in every respect. There could be seen everything connected with an electric railway, from a track-sweeper to a trolley-hanger, and the exhibition being free, was availed of by thousands of visitors, including many of the employees of the Boston Elevated Railroad Company, who were particularly interested in all they saw.

So far as the arrangements for the comfort and convenience of the delegates and of the exhibitors went, there was nothing that could have been carried out in a more painstaking and satisfactory manner. The Association had established a Bureau of Information in a handsomely decorated booth in charge of Mr. Robert H. Derrah. In this there was a private telephone, stenographers, writing material and a post office. The uniform courtesy shown by all in charge of the Bureau of Information deserves hearty commendation.

The feature of the convention was the large attendance of ladies—no less than 500 ladies' badges having been issued.

The press, as usual, was fully represented. "The Street Railway Journal" had a large, handsomely decorated booth, with their beautiful monster convention issue displayed on the outer walls. "The Street Railway Review" occupied a booth adjoining the Information Bureau. Their convention issue also was a most admirable and artistic production. Among the electrical papers presented were the "Electrical Review," "American Electrician," "Electrical World," "Western Electrician." The Electrical Engineer and "Electrical Age." Representatives were also present of "Power," "Railroad Gazette," "Engineering News" and other journals.

Exhibit Notes.

A. O. NORTON, Boston, Mass., exhibited a full line of the Norton patent ball-bearing lifting jacks and the improved "sure drop" track jack, ranging in capacity from 8 to 70 tons, a new feature being a traversing or replacing jack for street railway service. Mr. H. A. Norton was in charge.

THE DEARBORN DRUG AND CHEMICAL CO. was represented by their Mr. Carr, who had a remedy for every ill to which boilers are heir. Mr. Carr also had a few pocket match-boxes as souvenirs for the company's friends.

OHIO BRASS CO., Mansfield, O.—The products of this firm include a full line of overhead material bell metal bearings, saddlery hardware and trimmings, engine trimmings, including sight feed oil cups and a large variety of brass trimmings. The exhibit occupied a handsomely trimmed booth to the right on entering the exhibition hall and remarkable in the number and variety of pieces exhibited. These included a full line of overhead material, including the flexible brackets of the Wood type, of which this company makes a specialty. A special line of materials for figure 8 trolley wire, clamps, special clamps for double trolley wire, and a line of acid and sulphur proof hangers for use in coal mine haulage. The exhibit included a large number of samples of the insulation known as the "Dirigo," of which they make a specialty; a great variety of ears for pull off lines, a special locking device, consisting of cap and cone form of hanger; type D hangers having scollops and specially designed catch, which prevents the cup from becoming loosened

by vibration; feeder wire splicers up to 500,000 c. m. capacity; emergency splicers. Among the sundries we noted adjustable track brush holders and brushes, gongs, ratchet brake handles, snap switches, headlights, Eyanson quick brake switches, etc. Mr. C. K. King, secretary, and C. L. Wilkinson, special representative of the company, were in attendance.

GENERAL ELECTRIC CO.—At the end of the hall, where nothing intervened between the floor and the roof tree, an immense globe was erected by the General Electric Company to serve as an exhibit, not so much of its great facilities as of the world wide use of its apparatus. This company did not consider it necessary to make any special exhibit of its apparatus, as all the great dynamos now used to furnish current to drive the street cars of Boston were built in its works, almost every motor is of its manufacture, and with few exceptions, every switchboard and controller.

The huge globe, representing the earth, was built up of papier maché upon a frame work of wood, and rested upon a black pedestal picked out with gold. The continents and oceans were

EXHIBIT OF THE GENERAL ELECTRIC CO.

plainly depicted by the scenic artists of the Boston Theatre. The globe was built in 54 distinct sections to a scale of 312 miles to the foot, was 25 feet 2 inches in diameter, and weighed 3 tons. It stood on a pedestal 16 feet in diameter, and was placed in exactly the position occupied by the earth itself in the interstellar space, the north pole being indicated by an incandescent lamp of 100 c. p. Two thousand seven hundred yards of papier maché, in nine layers of 300 square yards each, were employed in the construction of the globe, the building of which occupied just two months.

Dotted over the globe, thickly in the United States, less thickly in Europe, and sparsely in the less civilized countries, were small incandescent lamps of different colors, each lamp representing the location of some city in which the General Electric Company has some typical installation. Four hundred lamps were employed. The installations included those for street car propulsion for mill or mine work, or for lighting purposes. No better idea of the extent to which American ideas on matters electrical have permeated throughout the whole earth, could possibly be gathered than from a glance at this globe, and the mind reverted to the names of Edison, Thomson, Van Depoele, Sprague, Brush and others whose practical genius made this world-wide use of electricity possible.

Each country was indicated by its national flag, and the Stars and Stripes fluttered not only over the United States, but also over Cuba, Porto Rico and the Sandwich and Philippine Islands. The interior was richly upholstered, the decorative color

scheme being worked out in pink and green. The air was kept cool by electric fans and the lighting of the interior was all indirect. The globe will remain in place during the Mechanics' Fair, and will then be taken down and sent to Paris, where it will occupy a prominent position in the Electrical Building, at the Exposition of 1900.

The space behind the globe was set out with comfortable chairs for the benefit of visitors. Here also was set up a model plant to show the practical working of the Thomson car recording meter, consisting of a G. E. 800 motor, and R 11 controller and the necessary resistances, the car meter, fuse and a form M circuit breaker. The load was applied to the motor by means of a brake working on a pulley keyed to the armature shaft. Behind this plant was an instrument board, on which were exhibited the latest types of astatic volt and ampere meters, inclined coil switchboard and portable instruments, motor-vehicle meter and edgewise ammeter, all grouped around a type M station recording wattmeter reading to 8,000 amperes. On an easel a framed sign showed the railroads in the vicinity of Boston employing General Electric apparatus and the details of their equipment. Above the instrument board hung another illuminated sign—the complement of the globe—setting forth the railway record of the company, which has manufactured

office; A. D. Babson, Baltimore office; H. T. Heywood, Atlanta office. The Supply Department, at Schenectady, was represented by J. B. Lovejoy, general manager; H. C. Wirt, engineer, and J. K. Aitken. The Railway Department, by W. B. Potter, chief engineer; F. E. Case, E. D. Priest, L. C. Batchelder and C. A. Barry; the Patent Department, by A. J. McDonald.

BARNEY & SMITH CAR CO., Dayton, O., manufacturers of trucks and cars, exhibited three types of trucks, one being their well-known single truck and the others Class H, double motor truck and the maximum traction double motor truck.

DUPLEX CAR CO., New York and Boston, exhibited a complete car of the duplex type, manufactured by the Briggs Car Company, of Amesbury, Mass. This car combined the principles of an open and closed car, being changed from one to the other very readily. For converting it into an open car the side panels, including the sash and glass, are slid upward and housed under the roof. The exhibit was in charge of J. A. Lowell, president; W. B. Crittenden, vice-president, and Mr. George Moore, inventor and patentee.

THE SAFETY THIRD-RAIL ELECTRIC CO., New York, exhibited a model of their system, with car one-sixth size, operating on a circular track about 80 feet in length, with turnout, one section being immersed in a tank of water to show that the

THE SAFETY THIRD RAIL ELECTRIC CO.'S EXHIBIT.

and sold up to September 1, 1898, 2,285 railway generators, aggregating 423,101 h. p.; 52,341 railway motors aggregating 1,270,865 h. p., and 50,000 series parallel controllers.

Let into the pedestal of the globe were two spaces fitted with shelves, on which were shown the most recent types of overhead material, circuit breakers, lightning arresters, etc. The entire convention hall was lighted from G. E. enclosed arc lamps.

Headquarters were established in the Hotel Brunswick, where in the Venetian room several albums containing photographs showing the wide diversity of General Electric work and a fine collection of medals and diplomas were set on the tables.

Mr. W. J. Clark, general manager of the railway department, had the interests of the General Electric Company in his care, and no complaint was heard of its hospitality. Mr. Clark was assisted by the following representatives of the company: Messrs. C. B. Davis, F. M. Kimball, C. C. Pierce, C. D. Haskins, S. B. Paine, G. E. Steele, of the Boston office; R. H. Beach, T. Beran, J. J. Mahoney, T. A. Branion, W. G. Bushnell, of the New York office; Theo. P. Bailey, of the Chicago office; G. D. Rosenthal, St. Louis office; H. J. Crowley, Philadelphia

car can be operated should the track become submerged. The exhibit also included the non-arcng switches, by which the current is cut out or let into the active rail. A full description of this Murphy system appeared in *The Electrical Engineer* of April 7, 1898. Capt. John McLeod Murphy, Mr. E. V. Baillard, Mr. William Devoe, Mr. John Cokeley and Mr. G. Kahn were in charge of the exhibit.

AMERICAN VITRIFIED CONDUIT CO., New York. The exhibit included single, triple, quadruple and six-duct sections in different lengths, so that the joints are easily broken. There was also a section of multi-duct conduit laid in position as it appears in the trench on a concrete bed, with manhole construction and manhole cover, one section being undermined to show the strength of the joints. The exhibit was in charge of Mr. C. J. Field, general manager and chief engineer of the company.

SANITARY ENGINEERING CO., Philadelphia, manufacturers of ventilated manhole covers, specially designed for electric conduit service. These covers are provided with valves and grooves, which allow the air to escape but do not admit moisture under any conditions. The valves are operated by the passing of

vehicles, and as each one is located in a funnel-shaped cavity as they operate the interior air is discharged and drives the moisture from the receptacle. These covers are so designed that they may be filled with any kind of paving to correspond with the street. The exhibit was in charge of Mr. Alfred B. Botfield, patentee.

WALKER COMPANY, Cleveland, O. This company's exhibit included a three-panel four-circuit switchboard, equipped complete in every detail for street railway power house, a case

EXHIBIT OF THE WALKER CO.

containing separate parts of armature and commutator construction, representing a complete winding, one of partial winding and one with commutator attached and one with bare core; two styles of motors 33 S., with new type of solenoid controller; a 15 L. motor, two No. 5 motors mounted on the Peckham trucks, the whole mounted on a 60-foot section of the underground trolley construction of the Love type. The exhibit also included a large number of the Walker enclosed arc lamps for 110-volt circuit. Mr. S. S. Short, Mr. H. McL. Harding, New York representative; Mr. C. H. Black, Mr. J. A. Anthony, Mr. M. D. Law, Mr. H. G. Issertel, Mr. F. W. Sawyer, of the Boston office; Mr. H. B. Gay, of the Baltimore office; Mr. R. A. Byrnes, of the Buffalo office; Mr. J. Holt Gates, of the Chicago office; Mr. N. F. Moon, Pittsburg office; Mr. J. N. Dodd and Mr. J. D. Moore were in charge of the exhibit.

PECKHAM TRUCK COMPANY, Havemeyer Building, N. Y. This exhibit included twelve trucks, representing every variety of the Peckham system of trucks, and occupied the largest

EXHIBIT OF THE PECKHAM TRUCKS.

space of any single exhibit at the convention. Some of the double trucks were equipped with motors of the Walker, General Electric and Westinghouse make. This firm are now making a specialty of their swing-bolster trucks for double truck cars, known as Type No. 14 A, No. 14 A extra heavy, No. 14 B short wheel base and No. 15. Besides the

trucks the exhibit included an equalizing brake shoe head, recently brought out by this company; also two types of maximum traction trucks known as No. 14 D 2 and No. 14 D 3. The exhibit was in charge of Mr. Edward Peckham, president; Mr. E. G. Long, vice-president; Mr. J. H. Hanna, manager; Mr. W. H. Gray, of the Chicago office; Mr. A. W. Field, of the Boston office; Mr. W. C. Rogers and Mr. George H. Bowers, of the New York office.

WESTINGHOUSE ELECTRIC AND MANUFACTURING CO., Pittsburg, Pa.—This company exhibited a 25 k. w. rotary transformer, changing direct current into alternating current, small alternating motor with attached exciter, an exhibition of practical operation of lightning arresters, also pneumatic switch and circuit breaker outfits. These switches are operated by compressed air at a pressure of about 80 pounds and have 2,000 amperes capacity. The operating pedestal contains ammeter, voltmeter switch, rheostat controlling handle and operating valves. The compressed air is furnished by a 2½ h. p. rotary air compressor furnished by the Westinghouse Air Brake Company, and the motor by the Westinghouse Electric Company.

There were also shown three standard railway motors, 12 A, 38 B with side bar suspension, and the most recent motor, No. 49, 35 h. p.; also four controllers, the K 10, K 11, K 12 and B 4, the latter for operating the electric brakes; the latest type of iron-clad diverters, and a new auto-canopy circuit breaker. This has a magnetic blow-out, which is very effective. A standard street car choke coil, with lightning arresters attached, was also

EXHIBIT OF THE WESTINGHOUSE ELEC. AND MFG. CO.

shown, and lightning discharges through lightning arrester by means of a static machine.

There was shown for the first time a fan motor, which has not yet been put on the market, but will be the coming season, several of which were in operation in the exhibition hall.

The most attractive and interesting feature of the exhibit, and which received the most attention from the delegates, was a plate glass sign consisting of three sheets of plate glass 30x72 inches, placed one above the other, on which were the words, "The Name of Westinghouse is a Guarantee," the letters being about four inches high. The letters constituting these words formed one terminal of a condenser, and the back of the plates being covered with tin foil formed the other pole of the condenser. This sign was operated by the company's high tension transformer, with 200 volts primary to 60,000 volts secondary, the controlling device of course being in the low tension circuit. The effect was an infinite number of zigzag sparks from three to twelve inches in length, radiating from the letters in every direction and interspersed with extra heavy sparks that emitted forked lightning, producing a rushing and crackling sound loud enough to be heard all over the building. The power expended varied from almost nothing to 15 k. w. as a maximum. This apparatus was devised and patented by Mr. C. E. Skinner, of the Westinghouse Company.

There were also exhibited 12 alternating enclosed arc lamps, six indoor type and six outdoor. These were operated from an auto-transformer, which delivered any voltage from 80 to 4,000 volts in steps of five volts. In connection with this exhibit the

Sawyer-Man Co. had a full line of incandescent railway lamps of all candle powers and colors, the company being represented by Mr. Harry C. Farnsworth.

The Westinghouse Co. was represented by Mr. Frank H. Taylor, general sales manager; Mr. L. E. Imlay, Mr. W. M. Alexander, Mr. N. W. Storer, Mr. H. D. Murdock, Pittsburg, Pa.; Mr. Maurice Coster, manager Chicago office; Mr. Charles A. Bragg, manager Philadelphia office; Mr. Calvert Townley, of the Boston office; also Mr. A. S. Brown, Mr. H. M. Southgate and Mr. W. W. Ward, of the same office; Mr. H. C. Farnsworth, of the Sawyer-Man Lamp Co., Boston; Mr. J. R. Gordon, Atlanta, Ga.; Mr. T. C. Frenyear, Buffalo, N. Y., and Ahern & Soper, Ottawa, Canada.

PETTINGELL, ANDREWS CO., Boston. As agents for the Okonite Company this firm exhibited a full line of Okonite wires and cables. Also the "O. K." wire for the Phillips Insulated Wire Company. The exhibit included a reel of cable of 500,000 c. m., and a marble switchboard equipped with a full line of railway and stationary quick knife switches. There was also a board equipped with different colored lamps of the standard railway signal, a new block system brought out and manufactured by J. A. Lakin & Co., Westfield, Mass. Other features of this exhibit were a large pyramid composed of cans and cases of metal polishes known as the "Brilliant," and a sample of the Kilbourne sand box or sand feeder for street cars. The special feature of this feeder is that the sand is pushed into the tube by means of a rubber diaphragm, which is pressed outward by means of a foot lever operated by the motorman. The exhibit also included a line telephone inclosed in a metallic case, designed for use on high speed railways. The telephone is manu-

EXHIBIT OF THE PETTINGELL, ANDREWS CO.

factured by Whitman & Couch, Boston. In addition a full line of overhead material manufactured by Macallen, of Boston; Lundell fans in operation, manufactured by the Sprague Company, and lightning arresters. The exhibit was in charge of C. B. Price, F. P. Price, J. E. Wilson, W. A. Peterson and W. J. Keenan.

A. O. NORTON, 167 Oliver street, Boston, showed track and car jacks of the ratchet and screw type. These are manufactured from 8 to 70 tons capacity and in forty styles, making a specialty of their replacing jacks. Mr. Norton was himself in charge of the exhibit.

AMERICAN RAILWAY SUPPLY CO., Park Place, New York, made a fine exhibit of cap and breast badges, including samples of the police badges supplied to the police force of New York. Mr. Walter Chur was in charge of the exhibit.

THE AJAX METAL CO., Philadelphia, Pa. This firm make a specialty of car, engine and machinery bearings, and the exhibit included samples of Ajax metal in bearings of every description and ingots of different kinds of metals, including a superior grade of babbitt and solders. Also lead covering for iron roofs and lead covered bolts and nuts for use on refrigerator cars and such cars that are subject to the action of moisture or acids. Mr. George E. Pratt was in charge of the exhibit.

ALBANY LUBRICATING COMPOUND AND CUP CO., New York City, manufacturers of the Adam Cook Sons' original Albany grease and the Albany electric motor grease, exhibited

samples in tin and glass cans. The exhibit was in charge of Mr. M. V. Peavey.

H. W. JOHNS MANUFACTURING CO., New York, exhibited samples of vulcabeston products for overhead and con-

EXHIBITS OF H. W. JOHNS CO. AND CREAGHEAD ENG. CO.

troller parts. Among the novelties was a new flexible bracket for side pole construction, the flexibility being gained by an attachment at the base of the brace. The exhibit also included a full line of car heaters of all the different types manufactured. The exhibit was in charge of Mr. H. C. Spaulding, of the Boston office, and A. Hall Berry, of the New York office. There were also representatives from the Hartford works.

THE CREAGHEAD ENGINEERING CO., of Cincinnati, O., made their usual large exhibit of their well-known "flexible brackets." These brackets are the standard method of construction used on high speed suburban work and centre pole construction in cities, and were shown in a great variety of forms, both plain and ornamental for wood and iron poles, being made of a special steel which withstands a strain double that of ordinary pipe, and, all fittings being made in wrought and malleable iron, it is impossible to damage them by the most severe service. This exhibit also included a very complete line of overhead material, trolley insulators, curve pull-overs, section insulators, insulated crossings, strain insulators, pole tops, pole cellars, malleable iron crossarms and crossarm clasps, eyebolts, turnbuckles, etc. The display was nicely arranged and in charge of Mr. G. R. Scrugham, superintendent of the company. The company's souvenir was a neat steel pocket-rule and case.

SAMPSON CORDAGE WORKS, Boston, Mass., exhibited

EXHIBITS OF SAMSON CORDAGE WORKS AND ASHTON VALVE COMPANY.

full samples of their solid braided cordage, making a specialty of their trolley and arc cords, of their well known "Spot" brand; also railroad signal cords, together with bell cord couplings,

socket snaps, cord grips and other fastenings. All the cords are treated with a waterproof finish, which insures long life. The exhibit was in charge of Mr. F. J. Coakley.

ASHTON VALVE CO., 271 Federal street, Boston, exhibited a very full line of Ashton pop safety valves and gauges, also water relief valves and cylinder relief valves, with a full line of pressure and vacuum gauges. Messrs. H. H. Ashton, C. W. Houghton and Albert C. Ashton were in charge of the exhibit.

GOLD STREET CAR HEATING CO., of New York, exhibited different types of car and office heaters, both stationary and portable, among the latter being a large upright heater with

EXHIBIT OF GOLD ELECTRIC HEATERS.

electric fan attachment for forcing the air through the resistance coils, designed to be operated from any line circuit. In the manufacture of these heaters the individual coils are supported by an enameled zig-zag rod. By this design the individual coils cannot become short-circuited and the wires cannot shift by the swaying action of the cars. These heaters are designed for three degrees of heat, which is regulated by a switch, so that in mild or extremely cold weather the required amount of heat can be secured without any serious loss of current. The exhibit was in charge of Messrs. E. E. Gold, J. E. Ward, E. H. Mossgrove and H. E. Beach.

ADAMS & WESTLAKE CO., Chicago, made a fine exhibit

EXHIBIT OF THE ADAMS & WESTLAKE CO.

of window shades, electroliers, headlights and a full line of car trimmings. The booth in which the exhibits were shown was modeled after a street car, with panels and windows of different widths on one side, double doors operated by different appliances at each end and one side of the booth showing only the posts, with curtains that come down to the floor, illustrating the use of these curtains on open cars. Among the novelties was what is known as the "Contra-Twist Double Door Hanger," con-

sisting of an inch and a quarter bar placed above the door, with a right and left thread each way from the middle, by which means the doors are readily opened and closed and are held permanently in any position, from one-half inch to full width, and cannot be closed by the swaying of the car on curves. They also exhibited the "horseshoe rail bonds," manufactured by them. The exhibit was in charge of Messrs. F. B. Jones, H. E. Keeler, William Bartholomew, Louis Gray and E. H. Stearns.

THE JOHNSON CO., Lorain, O., exhibited two trucks of the Dupont type, one single of 30 h. p., and the other for double truck cars of 50 h. p., both equipped with the Johnson motors. There were also two 35 h. p. motors and their No. 44 trolleys. The trucks were so mounted that the wheels could be put in operation, showing the complete operation of the trolley and motors. Also a large number of samples of special track work,

THE JOHNSON COMPANY, LORAIN, OHIO.

including crossings and switches. The exhibit was in charge of Daniel Coolidge, president; H. C. Evans, New York; Randolph Clitzen, Boston; O. C. Evans, Cincinnati; W. W. Kingston, Atlanta, and J. A. Rutherford.

BIBBER-WHITE COMPANY, 49 Federal street, Boston, exhibited a full line of bracket arms and line material of their own manufacture, together with headlights, a full line of switches, single and double throw, manufactured by the Hope Electrical Appliance Company, Providence, together with the New Haven registers; also, a full line of commutator bars and rail bonds, known as the "protected" type and manufactured by the Forest

EXHIBITS OF BIBBER-WHITE CO., R. D. NUTTALL CO., CHAS. N. WOOD ETC.

City Electric Company, of Cleveland; also a full line of trolley wheels and harps of their own manufacture. One of the novelties was a corrugated trolley pull, which, because of the corrugation, possesses unusual strength, while it is lighter in weight

than any other type of pull, weighing ordinarily only about 12 pounds, as against 22 of usual types. Their line material was shown in two types, form "G" and "D." Form D is cap and cone type and is made up in galvanized and black enamel finish. Form G is made up in four different styles, black enamel, galvanized, bronzed and agatized. The latter is something entirely new in this line and is like the agatized dishes used in cooking materials. This material that goes on the parts is a perfect non-conductor. In many cases it is not necessary to put in globe strainers, the insulation is so perfect. They also showed a full line of circuit-breakers and other goods manufactured by the Cutter Electric Company, of Philadelphia. They also exhibited two types of trolley bracket arms, one known as the "Adjustable Rigid," the other the "Adjustable Flexible," the flexible principle being secured by means of a strand of twisted wires attached to yokes, one at the end and the other at the middle of the arm. They had also telephone equipments for the use of the visitors. The exhibit was one of the most attractive of the entire show. It was in charge of Messrs. C. E. Bibber, president; A. L. Brown and David Dunn and Miss Anna Mendon, stenographer.

CHARLES N. WOOD, Boston, exhibited gears, pinions and bearings, manufactured by the R. D. Nuttall Co., of Allegheny, Pa., also trolley bases and poles, and trolley wheels manufactured by the same company. Mr. Wood, being New England agent for a number of manufacturing firms, had on exhibition goods representing the following: A full sample of registers, both stationary and portable, manufactured by the International Register Company; car heaters, manufactured by the American Electric Heating Corporation, of Boston; commutators for motors and generators of every description, of his own manufacture, and a track scraper, manufactured by the Monarch Stove Company, Mansfield, O. There was also a trolley pole, reel and catcher, manufactured by the Wilson-Thompson Company.

R. D. NUTTALL & CO., Allegheny, Pa.—The exhibit of this company, which was in connection with that of Charles N. Wood, included a very large number of gears and pinions of both cast steel and malleable iron, together with the trolley bases for different electric systems, also trolley poles and wheels and harps. The exhibit was in charge of F. A. Estep, president and treasurer; Chas. J. Mayer, agent for the Middle States; Geo. W. Provost, Pittsburg District; Edgar Newman, New Orleans; Arthur S. Partridge, St. Louis.

CROSBY STEAM GAGE AND VALVE CO., 93 Oliver street, Boston. This well known firm exhibited a full line of steam gages, valves, engine indicators, water columns and steam whistles. Among the specialties were specimens of spring

CROSBY STEAM GAGE AND VALVE CO.

seat, globe and angle valves; the special feature of these are the removable seats and discs. A marble gage board, including a set of four instruments—a clock, steam pressure gage, vacuum gage and revolution counter. Another specialty was a complete vacuum pump, with a mercury column, and the Crosby patent steam gage tester. The exhibit was in charge of Mr. Robert Pirie, the Boston representative.

ELMER P. MORRIS, of New York.—This exhibit included a full line of gears and pinions manufactured by the Simonds Manufacturing Co., of Pittsburg, samples of metals from Ajax Metal Co., of Philadelphia; three sizes Kosmic oil filters, manufactured by the Kosmic Oil Filter Co., of Easton, Pa.; eight different sized tubular side poles 30 feet long, made in various forms showing the construction of joints and patent lock swedge joint, manufactured by the Electric Railway Equipment Company, of Cincinnati. The exhibit also included a lot of grill

EXHIBITS OF STERLING ARC LAMP AND E. P. MORRIS.

work and bracket pole fittings, overhead material and car trimmings, manufactured by the same company, tapered steel trolley poles made by the Pittsburg steel trolley company, a lot of the Keystone Electric Instrument Co.'s meters, Sterling arc lamps, Garton-Daniels lightning arresters, Harrington Rail Bonding Co.'s system of bonding, Forest City Railway Co.'s protected bonds, Partridge Carbon Co.'s samples of carbon brushes, Christensen Air Brake Co.'s individual compressor and cylinder, which operated a whistle. Last, but not least, there was a miniature roof garden, with a trio of banjo artists, and over the door a suspicious looking placard which read, "Sterling X-Rays." The X-rays were absorbed without deleterious effects to any of the visitors, so far as we know. Mr. Elmer P. Morris was in charge, and Mr. Stevens looked out particularly for the Keystone Electrical Instrument Company.

STERLING ARC LAMP CO., New York City. This company exhibited twenty-six enclosed arc lamps of different styles and sizes, some of them being in use for illuminating other exhibits besides their own. There were five arc lamps in series for railway circuit, sixteen on low tension circuit, four alternating current. The exhibit was in charge of Mr. R. J. Randolph, general manager, and Mr. R. Schebauer.

VACUUM OIL CO., Boston, exhibited a case containing samples of their various brands of oil. The exhibit was in charge of Mr. E. A. Record.

JOHN D. REED, Boston, exhibited several specimens of the Reed rail joint. This is a three-bolted double base bearing beveled point joint, designed especially to restore pounded out rail ends. In connection with the joint was shown an entire metal system for railway construction, including drain chutes and cross gage bars.

M'GUIRE MANUFACTURING COMPANY, Chicago, manufacturers of 47 different kinds of single and double trucks, sweepers and car heaters. The exhibit included their latest style Columbia four-wheeled truck and a number of different styles of their heaters, one being the improved magazine heater. The outside exhibit consisted of a combined sweeper and snow plow, known also as the Columbia, which is manufactured for the Chicago City Railway Company. The exhibit was in charge of Mr. W. J. Cook, vice-president, and Mr. W. G. Hubbard, chief engineer.

LAP RAILWAY TRACK CO., New York.—This exhibit was in charge of Mr. T. H. Gibbon, chief engineer, and included a section of track of wooden rails illustrating the method of construction and uniting of the rails in position. In this construction the rails are rolled in two sections, so that when

in position the head of one overlaps the other, the joints being strengthened by side braces and interior upright, the weight resting on the upright and making so many contacts that bonding is not necessary. This system is braced laterally by flat tie rods, which are notched into both sections and fastened by bifurcated keys.

WM. H. GALLISON COMPANY, Boston, exhibited a large globe valve.

THE J. G. BRILL COMPANY, Philadelphia, made an excellent exhibit comprising two cars, one being a 28-foot standard closed car, such as used by the Metropolitan Street Railway Company, of New York City, and which they have settled upon as a standard. It was mounted upon their No. 22 trucks of the maximum traction type. This car was finished inside in what is known as selected silver ash, with Millen patented signs, Sterling brakes and Sterling registers; the seats were upholstered in handsome Wilton carpet. The car had Brill's patented angle iron bumpers, radiating draw bars, etc., complete. They also showed one of Mr. John A. Brill's latest inventions, viz., a convertible car. This is a combination open and closed car, the panels and sash of which slide up by an ingenious method into the

EXHIBIT OF BRILL TRUCKS.

roof without detracting from the appearance or shape of a standard closed or open car. The car has transverse seats, spring upholstered, covered with cane, decorated veneer ceilings, monitor deck roof, Brill's patented gates, radiating draw bars, pedal alarm gongs and angle iron bumpers. It was a pattern of car which attracted the attention of every delegate to the convention. There was also shown a Brill No. 21 E truck for single truck cars, being a non-pivotal truck with a solid forged axle box frame; Brill No. 27 perfect passenger truck, Brill No. 27 D truck, the standard truck of the Consolidated Traction Company, of Jersey City; Brill No. 27 F truck, a new pattern of trucks suspending the motors outside of the wheel base. In addition, they had on exhibition a Brill gate, radiating draw bar, sundry supplies, etc. In attendance were Mr. John A. Brill, Messrs. Samuel M. Curwen, George M. Haskell, George S. Hastings, W. S. Adams and W. H. Heulings.

WADSWORTH, HOWLAND & CO., Boston, manufacturers of coach, car and carriage paints and varnish, had two sides of their booth hung with different colored panels, highly varnished, and a pyramid of canned paints and varnish, the paints being ground either in japan or oil. Mr. H. A. Putnam represented the company at the convention.

THE INCANDESCENT ELECTRIC LIGHT MANIPULATOR AND CLEANER CO., Hyde Park, Mass., exhibited a device for cleaning and replacing incandescent globes where they are located out of reach. It consists of a pair of nippers operated by means of a flexible shaft. For cleaning, a mitten is placed inside the nippers. Mr. Joseph J. Dunn, manager of the company, was in charge of the exhibit.

AMERICAN MASON SAFETY TREAD CO., New York. This exhibit included samples of the Mason unwearable non-slipping stair tread, specially designed for car steps, running voids, car floors of open cars and stairs of all kinds. The material, which is manufactured in strips, consists of a base of steel ribs, with dovetail grooves, filled flush with lead, which is rolled in cold. Mr. John E. Walsh was in charge.

THE JANDUS ELECTRIC CO., of Cleveland, had a very attractive exhibit of their well-known enclosed arc lamps, and their series lamps on the 500-volt circuit attracted much attention. Their exhibit was in charge of H. T. Edgar, the New England agent, and the Creaghead Engineering Company, the central agents.

THE PARMENTER CO.'S LIFE GUARDS AND TRACK CLEANERS FOR STREET CARS, Cambridgeport, Mass. This concern exhibited a platform car, with tender in place, also wheel guard and track cleaner. The track cleaner is designed to remove snow and mud from the rail. Mr. George A. Parmenter was in charge of the exhibit.

HAM SAND BOX CO., Troy, N. Y., exhibited their No. 3 and No. 4 sand box, the latter being a modification of their well-known No. 1 box. In this the valve consists of a sharpened hoe, which pushes under the sand, and in drawing back hauls a certain amount into the tube. For use with this box sand does not have to be sifted. Mr. A. M. Wright was in charge of the exhibit.

POTTIER & STYMUS COMPANY, Lexington avenue, corner Forty-first street, New York, exhibited a reversible car seat, upholstered in cherry plush, especially designed for street railway service, arms being omitted. In reversing, the back turns over and rides at the same angle in either direction. The firm has recently contracted to supply the J. G. Brill Company with 1,050 seats in cherry plush. The exhibit was in charge of Mr. Frederick C. McLewee.

ALBERT & J. M. ANDERSON MANUFACTURING CO., Boston. This well known concern exhibited a full line of overhead line material, including a very large number of samples of the Aetna and Hecla railway insulators, Hancock and Ajax quick-break switches and "Ajax" lightning arresters. The exhibit also included enclosed arc lamps of the Monarch type and brass goods in drop-forgings and castings. Mr. Charles B. Pear was in charge of the exhibit.

COLEMAN FAREBOX CO., Tottenham, Ont. This company exhibited their portable farebox, which is provided with a handle and is carried by the conductor. He rings the bell by means of a thumb push-button. The box does not register the fares, but is burglar-proof and cannot be cheated. The hopper is provided with a system of steel teeth, which grasp the money or ticket as soon as it is partially inserted and prevents its being withdrawn. J. H. Coleman, one of the firm, was in charge of the exhibit.

BRADY METAL COMPANY, 100 Broadway, New York, exhibit consisted of street and electric car brass casting bearings and trolley wheels, Crowfoot and circular battery zincs. Three types of motor bearings were shown, pinion, armature and main axle bearings, with shell of brass and also of cast-iron, lined with genuine babbitt metal. Also check plates, anti-friction metals in pigs and Magnus metals in pigs. This metal has a record of running 426 miles in 425 minutes on a high-speed passenger locomotive without heating. The exhibit was in charge of Mr. D. M. Brady, Mr. C. P. King and Mr. C. M. Reubens.

WHEEL TRUEING BRAKE CO., Detroit, Mich. This company exhibited a new device for trueing up flat wheels while the car is running. It consists of a brake shoe made a little larger than ordinary shoes, of cast-iron, with chambers in the face of it, separated by an inch of solid metal. These chambers are filled with an emery composition, put in in a plastic state, which soon becomes very hard. In service the old shoe is removed and the emery shoe put in its place. The car is then continued in service and the wheel is ground down by the action of the shoe, a run of fifty to seventy-five miles being sufficient to true up a wheel, depending, of course, upon its condition. Dr. J. M. Griffin, president of the company, was in charge.

BEVERLY MACHINE WORKS, Beverly, Mass. The principal exhibits were their ratchet clutch brake handle and the ratchet clutch vertical brake wheel, the latter consisting of a double ratchet and beveled gear combined, and designed for service on vestibule cars. It has the ratchet principle, so that the brake may be set without turning the wheel clear round, maintaining the ratchet principle in all its operation and occupying not more than nine inches back from the dash. The concern also exhibited a full line of bronze car trimmings, including gongs, platform handles, bell-cord pulleys, door sheaves, sash locks and hinges, together with seat arms and backs. The exhibit was located in a prominent position and was in charge of Mr. John S. Baker, the proprietor, and Mr. William E. Bailey, superintendent of the works.

THE NEW PROCESS RAWHIDE CO., Syracuse, N. Y., manufacturers of rawhide pinions, were represented by Mr. A. C. Vosburgh.

BURDETT & JOHNSON, Boston. This exhibit embraced samples of cards with fancy and colored letters in great variety, and was in charge of Mr. A. F. Burdett and C. F. Johnson.

THE R. WOODMAN MANUFACTURING AND SUPPLY CO. This exhibit included conductors' punches, uniform buttons, speed indicators, car pushers and perforating machines. It was in charge of Messrs. R. Woodward and T. W. Wardley.

FORSYTH BROS.' CO., 1123 South Jefferson street, Chicago. This exhibit included car curtains and fixtures which the company manufacture in a great variety of material and figures. The samples were mounted in revolving and stationary cases and were in charge of Messrs. George E. Pratt and W. H. Forsyth.

SHAWMUT FUSE WIRE CO., Boston. The exhibit included a very large assortment of fuses of all sizes, from 1 to 1,500 amperes. The company also exhibited enclosed fuses for electric car heaters. Among the specialties were shown a number of knife switches. The exhibit was in charge of Mr. H. P. Moore.

EVANS ILLUMINATING CAR SIGNS, Portland, Me. Mr. W. R. Evans, the inventor, was in charge of this exhibit, which consisted of a revolving sign having three faces, each mounted on a pivot to the end frame in such a manner that the back face is always vacant, allowing the light from the car to shine through and illuminate one face.

COMPOSITE BRAKE SHOE CO., 620 Atlantic avenue, Boston, exhibited specimens of the composite brake shoes for steam and electric service, commonly called the "Compo" shoe. These are cast with round holes in the bases, which are filled with cork plugs or inserts. Mr. Frank Bruen, of Philadelphia, and Mr. W. W. Whitcomb, of Boston, were in charge.

NEW HAVEN CAR REGISTER CO., New Haven, Conn., exhibited all their different single, double and triple registers, so hung as to be operated by straps, cords and rods. The exhibit included the internal mechanism of a register still uninjured after having recorded 14,316,100 fares. The company was represented by Mr. Wm. M. Anthony, president; F. C. Boyd, vice-president, and J. S. Bradley, secretary and treasurer.

SHERBURNE & CO., Boston, Mass., manufacturers of construction tools and general railway supplies, exhibited a very large assortment of Buda improved track drills, rail benders, car replacers, track jacks, rail saws, hand and push cars, velocipede cars, etc. They are also selling agents for the Watson-Stillman Company, manufacturers of hydraulic tools and machinery, including jacks, rail benders, punches, etc.

CHARLES SCOTT SPRING CO., Philadelphia. The exhibit included all sizes of elliptical and spiral springs and sash and brush holder springs. The booth was surrounded by a chain of trolley pole springs in the national colors, hooked together. As a souvenir the firm gave out a small memorandum book, with handsome calf case and pencil and calendar for '98 and '99. The exhibit was in charge of Messrs. H. C. Johnston and D. S. Roche.

L. C. CHASE & CO., Boston, selling agents for the Sanford Mills. The exhibit included samples of all kinds of car plushes, plain and figured, showing a large number of designs for street railway seats; a case, showing samples of the different processes the mohair goes through from the time it leaves the goat's back until it is finished in the plush; also, a head and neck of an Angora goat as a wall ornament. Mr. F. B. Hopewell was in charge of the exhibit.

KNITTED MATTRESS CO., Canton, Mass. The exhibit included matting and cushions of different thickness, made of pure white cotton, knit into a netting or web, without any twist in the material, so that the natural softness of the fibre is retained, combined with great elasticity. In the manufacture of car cushions and backs the padding takes the place of curled hair. The exhibit was in charge of Mr. George Frederick Sumner, one of the principals of the firm.

SWIFT'S ILLUMINATED REVERSIBLE SIGNS, Boston. The signs exhibited by this company are mounted on a miniature car roof and so connected by shafts and beveled gear that the four signs can be revolved at one time by means of a short horizontal crank mounted under the hood. Each sign is provided with an incandescent lamp placed in a horizontal position in such a manner as to illuminate the outside face. Mr. W. H. Swift, patentee of the sign, was in charge of the exhibit.

THE HIPWOOD-BARRETT CAR AND VEHICLE FENDER CO., Boston, exhibited a small model of car with fender attachment. The exhibit was in charge of Mr. George Hipwood and J. W. Barrett.

A. B. HERRICK, 120 Liberty street, New York, exhibited a complete testing set for street railway work. This set was described and illustrated in *The Engineer* of September 8. Mr. Herrick himself was in charge of the exhibit.

RUSSELL CURVE-TAKING TROLLEY HARP, Watertown, Mass. This is a jointed harp, which allows the trolley wheel to cant over at any angle while rounding curves. The exhibit included a number of harps, and was in charge of Mr. W. H. Russell, inventor.

F. H. NEWCOMB, manufacturer of uniform caps of all types, was in personal charge of his exhibit. The hats on exhibition to the number of forty-two were in a neat double-deck glass case and were shown off to excellent advantage. The principal sales-room is at 13 Astor Place, New York, and the office and factory are located at 136 Flatbush avenue, Brooklyn.

PEARSON JACK CO., 64 Federal street, Boston. This firm exhibited samples of their 60-pound jacks of from 20 to 25 tons capacity. Also, the 30-pound jacks of two types, designed to work with either bar or ratchet, and which are made in different lengths, according to the height of the car to be lifted. These jacks are operated by means of a differential screw. Mr. A. H. Richardson and T. Edward Tuttle were in charge of the exhibit.

JOSEPH DIXON CRUCIBLE CO., Jersey City, N. J. This exhibit embraced samples of such products as are suitable for use in street railway service, and included the noiseless wood grease for gears and pinions, the perfect lubricant, consisting of pure flake graphite, which, being mixed with grease or oil, increases the lubricating properties to a high degree, and is designed for use on armature bearings, air-brake parts and, in fact, all machinery. The exhibit was in charge of Messrs. A. L. Haasis, J. H. Baird, George E. Long and E. A. St. John.

THE PLASTIC RAIL BOND. Mr. Harold P. Brown, the inventor of the bond, and Mr. Charles H. Wilson, New England agent, were in charge of this exhibit, which consisted of a great variety of rails, bonds and appliances, which were shown in two large glass cases. The exhibit was located near the middle of the hall and received a great deal of attention. Not only the plastic bonds, but other types for particular conditions of rail, were also shown. The exhibit also included fishplates, with the bond attachment, that had been in service three years or more, and one that had been preserved intact after being under water for two years.

KEYSTONE ELECTRIC INSTRUMENT CO., Philadelphia, made a large exhibit of instruments, including ammeters and voltmeters. One panel of the exhibition board contained a sample of all the different types of meters manufactured and also a sample of the portable instruments for general testing work, the cases finished in nickel, brass and copper. Some of the claims made for these instruments are that they have no permanent magnets and no springs, so that there is nothing about them that can get out of repair or deteriorate. The exhibit was in charge of Mr. J. F. Stevens, president of the company.

STANDARD THERMOMETER AND ELECTRIC CO., of Peabody, Mass., made an exhibit of their "Midget" and enclosed arc lamps for all circuits. There were shown several designs of fancy covered lamps, which were used for lighting the gallery evenings on a 100-volt direct current system. Several of the lamps were fitted with large opal shades in place of the ordinary outer globe. It was particularly noticeable that the effect of a full-ground outer globe was pleasant to the eye without detracting from the efficiency of the light. The exhibit was in charge of Mr. M. L. Livingstone, assistant manager, and Mr. J. H. Hallberg, electrician and designer of the "Midget" lamps.

MEAKER MANUFACTURING CO., North Chicago, exhibited different types of portable and stationary registers, making a specialty of their new combination register, which combines letters and figures in the record and serves as an additional check on the conductor and bookkeeper, as the record must be interpreted from the key, which is furnished to the manager only. It also bars the public from knowing the business of the company. A new and handsomely designed pamphlet, illustrating and describing the register, was first presented at the convention. The booth was trimmed and decorated in the national colors. The exhibit was in charge of Mr. J. W. Meeker, president, and Mr. George Bean, vice-president.

CHARLES BACON, Boston, exhibited samples of non-slipping step covers, known as the Lyte steel and lead woven tread.

THE PANTASOTE LEATHER CO., New York and Chicago, exhibited Pantasote fabrics for curtains, upholstering and parlor hangings.

BROWNELL CAR CO., St. Louis, Mo.—This company made no exhibit, but was represented at the convention by Mr. F. B. Brownell.

AMERICAN RAIL JOINT MANUFACTURING CO., Cleveland, O., exhibited a full line of their malleable self-locking rail joint, designed for both T and girder rails. The exhibit was in charge of Mr. W. E. Ludlow and T. V. Church, the Western representative.

THE W. T. VANDORAN COMPANY, Monadnock Building, Chicago, exhibited the draw-bar of the same name; also a universal ball joint for draw-bar attachment and a draught appliance, which consists of a peculiarly designed spring that allows some flexibility in starting. Also a book of blueprints, showing in detail the nine different sizes of couplers manufactured by the company. Mr. Vandoran himself was in charge of the exhibit.

ROOKE REGISTER COMPANY, Peoria, Ill. A portable register of novel design was the principal exhibit made by this company. The register is a small, nickel-plated machine, with a hopper in the top, is carried in the hand and is provided with a lever, which is operated by the forefinger. As the passenger drops the nickel into the hopper the machine automatically registers and rings the bell; at the same time the hopper is closed. The conductor then presses the lever, which opens the hopper and prepares the machine for the next nickel. The exhibit was in charge of Mr. George F. Rooke.

CONSOLIDATED CAR FENDER CO., Providence, R. I., manufacturers of the Providence fender and wheel guards. The exhibit included eight fenders and a table exhibit of a large number of attachments such as are employed for attaching the fender to different styles of cars. Two of these were fancy fenders, designed for parlor and directors' cars, one being in bronze, the other white enamel. The third was the practical type, such as are now used on more than seventy street railways of this country, aggregating more than 6,000 fenders. The exhibit was in charge of Col. A. C. Woodworth, general manager; A. C. Woodworth, Jr., and G. H. Hale.

STANDARD UNDERGROUND CABLE CO., Pittsburg. The exhibit of this concern included samples of electric light cable and underground feeder cables for street railways. Also samples of submarine cable and patent telephone cables. A large number of samples were given out as souvenirs. The company claim to have filled the largest contract that was ever let in the world for feeder cable. This included an order amounting to \$950,000, supplied to the Philadelphia Traction Company. The exhibit was in charge of Mr. T. E. Hughes, of Philadelphia, and Mr. George L. Wiley, of New York; also the treasurer of the company, Mr. Frank Reinhart, who was accompanied by Mrs. Reinhart.

CONSOLIDATED CAR HEATING CO., Albany, N. Y. This company made a fine exhibit of heaters designed for use under cross seats and side seats, together with regulating switches. An interesting feature of the exhibit was two heaters that have been in service on the cars of the Albany Railway since 1893. These heaters were in action and the voltmeter showed that they took exactly the same amount of current as when new. A bank of six heater cases was exhibited, in which incandescent lights were substituted for the heating coil and which were lighted in succession to show how the coils could be governed depending upon the weather, so that the consumption would be 3, 5, or 8 amperes, depending upon the combination.

BILLINGS & SPENCER CO., Hartford, Conn. This company exhibited a full line of drop forged commutator bars, embracing about 200 specimens, among which was a specially large segment weighing 24 pounds, designed for one of the large Niagara Falls generators. The exhibit also included samples of the drop forged cases for the Lundell motors. The literature given out included two catalogues, one issued in September and devoted entirely to commutator segments for stationary machines, illustrating over 200 patterns of commutator bars. The other, a catalogue of commutator segments designed for all the standard street railway motors, both catalogues being very handsome publications. The exhibit was in charge of Mr. H. E. Billings, Mr. F. C. Billings and Mr. W. B. Post.

PAGE IRON WORKS, of Chicago, manufacturers of special work, exhibited photographs only. The firm was represented by E. S. Nethercut, engineer.

E. T. BURROUGHS CO., Portland, Me., exhibited in revolving cases a full line of their car shades and curtains with the fixtures. The exhibit was in charge of Mr. H. H. Russell.

THE WILLIAMS TRUSS JOINT RAIL CO., Chicago, exhibited specimens of the joint attached to T and girder rails. The exhibit was in charge of Mr. John H. Williams, inventor and owner, Boston.

THE BOSTON ARTIFICIAL LEATHER CO.'S exhibit included six railway cross and side seats covered with samples of their material in different colors. The exhibit was in charge of Mr. Walter N. Dole and Mr. Albert E. Prince.

F. H. THOMPSON, Portland, Me., exhibited samples of his car seat springs, known as Thompson's perfecting spring cushion, designed for carriage and street railway service. Mr. Thompson, the inventor and manufacturer, was in charge of the exhibit.

THE FOREST CITY ELECTRIC CO., Cleveland, O., exhibited samples of drop forged commutator bars and protected bonds, also a sample of insulating varnish, manufactured by the Sterling Varnish Company, of Pittsburg, Pa. The exhibition was in charge of John C. Dolph.

WEBER RAILWAY JOINT MANUFACTURING CO., New York, exhibited samples of the Weber joint, the particular features of which are that a wooden cushion is employed between the fish-plate and the rail. The exhibit was in charge of Mr. Richard Devens, engineer of the company.

MR. WILLIAM F. ELLIS exhibited samples of the continuous rail joint, the Sternberg bolt and the Goldie claw shoulder tie-plates, which are used exclusively in the construction of the Boston subway. Samples were shown of steel car axles manufactured by Dilworth, Porter & Co., of Pittsburg.

CAMBRIA IRON CO., Philadelphia. This exhibit included a full line of T-rails, girder rails, fishplates, guard rails and such material as is generally used in track work. There were drawings of a large number of rail patterns from 8 to 110 pounds per yard. The exhibit was in charge of Mr. W. A. Washburn, the New York agent.

BETHLEHEM FOUNDRY AND MACHINE CO., South Bethlehem, Pa., exhibited a new trolley base, the peculiar feature being that it has a double set of springs, which, in operation, are under tension instead of compression, which avoids any set in the springs. The exhibit was in charge of Mr. R. S. Bishop. New York representative.

THE STANDARD AIR-BRAKE COMPANY were represented by Mr. J. R. Ellicott, Mr. Bacon, Mr. Ball, Mr. McCutchin and Mr. Petty. No exhibit was made in the hall, but the delegates were invited to inspect their brakes now working very successfully on twelve cars of the Commonwealth Street Railway Company, of Boston.

ALLEN & MORRISON BRAKE SHOE CO. exhibited a new composition shoe that seems particularly adapted for street car service, giving a very high braking power and a very small wear on the tread of the wheel. The manufacturers claim that it is noiseless and prevents the wheels from skidding. The company were represented by Mr. T. V. Church.

J. P. SJOBERG & CO., New York, exhibited samples of street car woodwork, the specialty being a pair of pillars for closed cars provided with sash and blinds and showing their patent sash holders. The exhibit was in charge of Mr. W. J. Walker, formerly connected with the John Stephenson Company, and therefore well known to the railroad fraternity.

AMERICAN BRAKE SHOE COMPANY, represented by the Ramapo Iron Works. This exhibit included the "Diamond S" brake shoe, manufactured by the Ramapo Iron Works, consisting of a cast-iron body enclosing a bundle of expanded sheet steel strips. The exhibit was in charge of Mr. William F. Ellis, the New England agent, and Mr. F. W. Sargent, of Chicago.

JOHN F. OHMER REGISTER CO., Dayton, O., exhibited a section of car equipped with one of their classified registers designed to register eight different fares. The fares are not only recorded by totals in the register, but also are printed on a sheet within the register, which materially assists in the bookkeeping, as all possible reckonings can be made from the sheet, which is an additional tally on the conductor. This register is really a system of registry and bookkeeping. The exhibit was in charge of Mr. John F. Ohmer.

DUFF MANUFACTURING CO., Allegheny, Pa. This exhibit included four jacks of different sizes of the Barrett compound and lever track jacks.

THE ROCHESTER HOSE BRIDGE CO., Rochester, N. Y., exhibited samples of their folding hose bridge, the exhibit being in charge of Mr. Joseph P. McMahon.

MCCARDELL, WEST & CO., Trenton, N. J., manufacturers of the Trenton trolley or tower wagon, showed a fully equipped wagon, Mr. McCardell being in charge.

MASSACHUSETTS MOHAIR PLUSH CO., Boston, exhibited a large line of plushes of different colors and figures, including the Boston Elevated Railway standard.

THE REED MANUFACTURING CO., Erie, Pa., exhibited an automatic self-adjusting pipe wrench of different sizes, working readily on any pipe from $\frac{1}{2}$ inch up to 4 inches.

DE WITT'S COMMON SENSE SAND BOX, Lansingburg, N. Y. This exhibit consisted of two types of their well known boxes, Mr. De Witt himself being in charge of the exhibit.

WHELOCK ENGINE CO., Worcester, Mass., manufacturers of the Greene-Whelock engine. This exhibit included a plug, with valve system complete, for a 24x42-inch engine. Mr. Charles C. Hardy was in charge of the exhibit.

MEROY VITRIFIED CLAY CONDUIT, New York and Chicago, exhibited samples of the multiple duct conduits as employed on the lines of the Metropolitan Street Railway Company, of New York. Mr. McRoy was in charge.

FALK MANUFACTURING CO., Milwaukee, Wis., exhibited a number of samples of the cast-weld joint, one a section of girder rail showing a joint after four years of service. The exhibit was in charge of Messrs. E. A. Wurst, Clement C. Smith and H. L. Prather.

THAYER & CO., Boston, represented the Aultman & Taylor Manufacturing Company, Mansfield, O., manufacturers of horizontal and vertical water tube boilers of the Cahall type. The exhibit included a header cast from flowed steel and a swinging manhole plate, together with drawings of the boilers.

CORNING BRAKE SHOE CO., Buffalo, N. Y., exhibited samples of their brake shoe, the principal feature being that the centre is an irregular mass of soft iron, which is cast first and the body of the shoe molded around it. The exhibition was in charge of Mr. Francis Granger, Eastern sales agent, and H. T. Mercur, general sales agent.

METHUEN ELECTRIC CO., Methuen, Mass. Samples of the company's new insulating connections were on exhibition. These are designed for connection between the motor and car wiring and take the place of the cumbersome method of soldering and taping, the connections being broken and restored in a very short time. The exhibit was in charge of Mr. C. D. Holman.

WM. H. BAILEY, Boston, New England agent for the Tonkin patent internally fired water tube boiler. The exhibit included a stationary boiler mounted in the power room of the Mechanics' Institute Building. After mounting the boiler was tested and a record of the test published in the circular given out at the Convention. Mr. Bailey was personally in charge of the exhibit.

BOARDMAN-TUCKER CO., Boston. This exhibit included special telephone apparatus designed for street and steam railway work, a special feature being a line telephone fitting in a cast-iron weather-proof case, designed to be attached to a pole along the line and containing all the necessary appliances; also others for office and desk work. The exhibit was in charge of Mr. A. F. Boardman.

WAGNER ELECTRIC MANUFACTURING CO., St. Louis. The exhibit included illuminated dial, dead-beat indicating instruments, a new line of carbon brake switches, two patterns of the standard Wagner transformers, Type F and Type G; also photographs illustrating some of the largest switchboards that have been manufactured by the company. Mr. E. H. Abadie, of St. Louis, and Mr. H. M. Mayo, of the Boston office, were in charge.

STERLING SUPPLY MANUFACTURING CO., of New York. This exhibit included a full line of fare registers known as the "Sterling," one of the latest being a double register on which two fares or tickets and fares can be recorded. Also a full line of overhead insulating material, safety brakes, the Sterling sand box and fender and a large number of drop forge commutator bars. Mr. F. A. Morrell and Mr. L. D. Nelson were in charge of the exhibit.

HEYWOOD BROS. & WAKEFIELD CO., Boston, exhibited car seats, both single and double, rattan hand sweepers and brooms; also a sample of the crude rattan used in the manufacture of snow sweepers. The type of seat exhibited is known as the Henry seat. The exhibit also included cocoa matting designed for car floors and cane webbing for car seats. Mr. Fred H. Henry and Mr. Clifford L. Lougee were in charge.

DUQUESNE FORGE COMPANY, Pittsburg, Pa. The exhibit of this company included a full line of forged gears. These wheels differ from all other railway gears in that the rim is forged or rolled straight in the form of a channel beam, after which they are bent to a half circle, when cast spokes are attached and the teeth are milled in the surface the same as in the manufacture of cast gears. The exhibit was in charge of Mr. J. B. Van Wagener, of Pittsburg, selling agent.

BEMIS CAR BOX CO., Springfield, Mass.—This exhibit included a standard single truck and their No. 37 pivotal double truck. The special feature of the truck exhibited is the long elliptical spring at the ends, which increases the spring base without lengthening the truck. The feature of the double truck is that the car is mounted low without having to cut out the running board. The exhibit was in charge of Mr. Geo. M. Hoadley, general manager, and Edward N. Richards, superintendent.

STANLEY & MILES, Whitman, Mass., exhibited their emergency brake as designed for street cars, the particular feature of which is an automatic appliance for emergency stops. By pressing down on the end of the handle a spring is released which applies the brake. For ordinary stops the handle is used as with other crank brakes. Another feature of this brake is that no chain is employed, but the power is obtained by means of a screw through a bell crank lever. The exhibition was in charge of Mr. J. E. Miles.

ROCHESTER CAR WHEEL WORKS, Rochester, N. Y., exhibited steam and street car wheels loose, mounted on special stands, also several types of wheels mounted on axles, including wheels of 15 to 40 inches in diameter. The particular feature of these wheels is that they are cast in the bar contraction chills, after which they are machined. The 40-inch wheel is specially designed for electric locomotive service. The exhibit was in charge of Mr. Frank D. Russell, Mr. George C. Morse and Mr. A. H. Strickland.

WM. WHARTON, JR., & CO., of Philadelphia. This company's exhibit included frogs, switches and mates and other special goods generally known as manganese steel special work. The unbroken main line cross-over was also a special feature of the exhibit. Another special feature of the exhibit was the Pennsylvania Railroad standard three-rail crossing. The firm was represented by Mr. Wharton, Mr. Howe, Mr. Angirer and Harrington, Robinson & Co., New England agents, Mr. J. B. Robinson being in charge.

COLUMBIA MACHINE WORKS, Brooklyn, N. Y., exhibited a line of commutators, made up from their own drop forged bars, car trimmings, journal bearings, pinions and gears. Among the specialties were their adjustable controller handle, the particular features being that it is always tight on the spindle and prevents the wearing of the spindle, thus giving always a positive motion. Among the specialties in overhead work was a 4-point pull-off or anchor, so designed that should the trolley leave the wire it cannot possibly catch the guide on either side. The exhibit was in charge of Mr. W. R. Kerschner, selling agent; Mr. J. G. Buchler, senior member of the firm, and Mr. J. W. Grady, superintendent.

NEW YORK CAR WHEEL WORKS, Buffalo, N. Y., manufacturers of machined car wheels for steam, electric and cable service, had a number of standard electric wheels mounted on their special cold rolled axles and loose wheels of various sizes and types. A new style of wheel was shown for interurban service where cars run at high speeds, the wheel being made with a single plate instead of with open spokes. The company also had several loose axles of special quality, of which they furnished some 10,000 for electric service. Also standard 1-inch test bars for showing the transverse strength of the metal in the wheels, and their chill test pieces, which give depth and hardness of chill, together with the sections of the tread and flange of the various sized wheels. The exhibit was in charge of Mr. J. J. Granger, of New York; Mr. Douglas Campbell, of Pittsburg; Mr. C. L. Pullen, of Philadelphia; Mr. Pemberton Smith, engineer, of Buffalo.

THE DIAMOND STREET IRON CO., Wilmington, Del., exhibited the Churchill rail joint for T and girder rails.

JAMES HITCHCOCK exhibited a reversible car seat, which is operated without turning the back. The seats are upholstered in rattan and plush and are manufactured at North East, Pa.

JOHN C. CURTIS, Chicago, exhibited the Lawton peerless fender. This is a scoop spring fender, which is raised and lowered by means of a wire cord and shaft operated by a crank handle.

PENNSYLVANIA CAR WHEEL CO., Pittsburg, exhibited a full line of motor and trail car wheels. This company manufactures wheels for any kind of service in any diameter from 12 to 42 inches.

D. C. SWEET, Springfield, Mass., exhibited car wheel grinding machines full size. This machine is so designed that the wheels may be ground over a pit in any part of the car house, being operated by the car motor itself. Mr. Sweet was himself in charge of the exhibit.

THE TAYLOR ELECTRIC TRUCK CO., Troy, N. Y., exhibited several trucks, both single and double, one of the single trucks embodying all the latest improvements. The exhibit was in charge of Mr. John Taylor, manager; Mr. Robert Kasson, foreman, and Mr. Aubrey Tupper, of the office staff.

R. BLISS MANUFACTURING CO., Pawtucket, R. I.—The exhibit included the Woods patent platform gate mounted in position on the platform of a car. Over 4,000 of these gates are operating on the street car lines of Boston. The exhibit was in charge of N. H. Colwell, manager, and Charles O. Wood.

THE BALTIMORE CAR WHEEL CO., Baltimore, Md., exhibited both their single and side bearing double trucks of the Lord Baltimore type. The special feature of these trucks was a new adjustable axle collar. The exhibit was in charge of J. Paul Baker, secretary, and A. E. Baker, representative in London.

SPRINGFIELD MANUFACTURING CO., Bridgeport, Conn., exhibited emery and corundum wheels and over 250 varieties of grinding machines, dry grinders, roll grinders, surfacing machines, tool grinders, universal grinders, etc. The exhibit was in charge of G. W. Jackman, manager, and Mr. G. E. Martin, mechanical engineer.

THE JOHN STEPHENSON CO., car builders, New York, exhibited a model $\frac{1}{4}$ size of a Broadway cable car with double doors and gates, the safety brake, Providence fender, mounted on Peckham truck and equipped with Sterling registers and headlights and lamps. The exhibit was in charge of Mr. Henry Woods, who designed and made the model.

ROBINSON ELECTRIC TRUCK AND SUPPLY CO. The exhibit included models of both types of trucks, the well-known electric truck and the new six-wheel radial truck for passenger and palace car service. The exhibit also included the Robinson interlocking truss rail joint. In connection with the exhibit was printed matter describing a new departure in electric railway construction, designed as a suggestion for converting steam railways to be operated by electric power. Mr. Wm. Robinson, general manager of the company, was in charge.

CHRISTENSEN ENGINEERING CO., Milwaukee. This exhibit included a No. D 4 air compressor in operation, this being the type of compressor used on the Metropolitan West Side Elevated, of Chicago, and the B. & O. Belt Line, of Baltimore. There was also a No. B 2 air compressor in operation, the current to the motor being controlled by an automatic cut-out. The third exhibit consisted of a No. AA 1 air compressor designed for double-truck high-speed heavy cars. Mr. N. A. Christensen, Mr. S. W. Watkins, Mr. Frank C. Randall and Mr. W. J. Davidson were in charge.

THE PENNSYLVANIA STEEL CO., Steelton, Pa., exhibited samples of their "Adamantine" cast steel special work and track fixtures, the most interesting feature being a 10 inch switch, mate and frog manufactured for the Boston Elevated Railway Co., the Pennsylvania Steel Co.'s Adamantine work being the standard on this road, as well as most of the other large roads of the country. They were represented by Messrs. Charles S. Clark and Wm. E. Cuntz, Boston agents; Mr. Stephen A. Baldwin, New York agent; Mr. C. W. Reinochl, and Mr. Mason D. Pratt, chief engineer.

NEW YORK SWITCH AND CROSSING CO., Hoboken, N. J. This exhibit included a specimen of their special work for crossings and switches, the particular features of which are that the centres are of chrome steel cast in position. The most interesting feature of the exhibit, however, was their electric

switch in operation, so arranged that the entire mechanism could be inspected. This switch is designed to be operated by the current, which is under control of the motorman. Exhibit was in charge of Mr. W. C. Wood, president; Mr. L. E. Robert, secretary, and Mr. A. J. Baldwin, electrician.

TAUNTON LOCOMOTIVE MANUFACTURING CO., Taunton, Mass., manufacturers of snow plows for street railways, sprinklers, transfer tables and brake handles. The exhibit included three snow plows. First the double type share plow for use in city work, weighing $8\frac{1}{2}$ tons. The second, or heavy nose car, weighs $10\frac{1}{2}$ tons, and is claimed to be the heaviest appliance of its kind ever put on the market. It is designed for the heaviest kind of drift work, and is recommended only for extreme service. The third plow is the standard nose plow, which weighs $8\frac{1}{2}$ tons, and is claimed to be heavier than any nose plow now on the market. The last two plows are for single track work. The wing mechanism on the standard nose plow is like that on the double track share. The digger mechanism has been designed with special care to stand the terrible punishment which diggers must receive, and steel coil springs give the necessary yielding feature if the diggers strike the end of a switch or a guard rail. The company also exhibited the Collins noiseless ratchet brake handle. Mr. Wm. R. Billings, treasurer, with the selling agents, Messrs. Wendell and McDuffee, were in charge of the exhibition.

Independent Telephone Association Meeting.

It having been announced in one of our contemporaries that the next meeting of the Association will be held in June, 1899, we are requested to publish a denial of this report, as it was unauthorized. Preparations are now being made for a big meeting in October, although it is not fully determined.

The Street Railway Accountants' Association Meeting.

The Street Railway Accountants' Association of America held their second annual meeting in Boston at the same time as the American Street Railway Association, occupying a hall adjoining that of the former. The following papers were read: "Car Mileage—How Arrived At and Its Use," by A. H. Ford; "Statistics, Their Use and Abuse," by E. D. Hibbs.

The standing committee on "A Standard System of Street Railway Accounting, Covering the Classification of Operating Expenses, Classification of Construction and Equipment Accounts and Form of Annual Report," handed in its report, which was discussed at length.

A feature of the accountants' meeting was the exhibition of blanks and forms employed by a large number of street railway companies, which were spread out on tables in an adjoining room.

The Maritime Electrical Association.

The first convention of the "Maritime Electrical Association" will be held at Halifax, N. S., on September 27. A number of papers have been prepared, a good programme arranged and a large number of members are expected to attend. This association, which has only been in existence about six months, has a large membership list, and gives promise of doing a good work.

Association of the Edison Illuminating Companies.

In connection with their fourteenth annual convention, held at Sault Ste. Marie, Michigan, on September 12, 13 and 14, the above association have issued a very handsome booklet illustrating scenery around this beautiful and important manufacturing centre, as well as giving the members useful and valuable information regarding the place and its surroundings. On the cover is a half-tone illustration of the steamer Northwest entering a lock; then follows a history of the Edison Sault Ste. Marie Electric Company, a sketch of Sault Ste. Marie, Michigan's oldest

settlement, some interesting facts of the historic Fort Brady and details about the present city of Sault Ste. Marie, with its 10,000 people and world-wide fame. Then comes a description of the celebrated locks and details about the water power in that neighborhood, 20,000 h. p. of which is now being developed to be devoted to the manufacture of calcium carbide. Other power companies are now developing 100,000 additional horse power. The booklet is profusely illustrated and neatly bound with a white silk ribbon. It is a great credit to this enterprising association, whose annual meeting, judging from the preparations and the papers to be read, will be a most entertaining, instructive and valuable one. The paper by Messrs. J. W. Lieb, Jr., J. Van Vleck and Arthur Williams on what they saw abroad on their recent tour will certainly be awaited with a great deal of interest and anticipation.

Free Guide Book.

A very handy and comprehensive guide to Boston has just been published by the Mechanics Fair Committee and is being eagerly sought by intending visitors to the exhibition, as well as by others who contemplate a trip to Boston. The book is up-to-date, with readable descriptions of the city's most notable points and objects of interest, and will be found very handy for reference.

The big building of the Massachusetts Charitable Mechanics' Association on Huntington avenue is rapidly being prepared for the exhibition which will open October 10 and which will undoubtedly prove the most important and interesting ever given by this organization.

The Committee has decided that anyone sending a two-cent stamp to Henry D. Dupee, secretary, Mechanics Building, Boston, will receive by return mail a copy of this valuable little guide-book free of charge.

Spiral Versus Coil Springs.

I WRITE to protest against the continued and erroneous use of the word "spiral" in describing coil springs. A spiral is a plane figure, and a spiral spring must and can only be a flat spring such as a watch or clock spring. Coil springs are true helices, and should so be denominated. In perusal of the description of the Mechanicville Transmission Plant, which appeared in your issue of September 1, the word "spiral" occurs in describing the springs of the plunger switches. The construction, however, would indicate that a coil or helical spring was used in this device. I know, of course, that the term "spiral" is largely used in connection with helical figures. We have "spiral" springs, "spiral" packing, and so on, but this usage by no means makes the term a correct one in these instances, and when a description of a spiral or clock spring is intended, the reader is puzzled and in doubt unless the construction of the device in which it is used is obvious.

This misuse of the word I have often seen in the class of technical journals that are filled chiefly by letters from Heaven-born engineers, who leave the subject under discussion to descend to personalities, and there it is to be expected, but such careless nomenclature is utterly at variance with the standard of The Electrical Engineer, and I must confess that I was somewhat surprised at seeing the term misapplied in the article mentioned. It is high time that this misuse be corrected, primarily because it is wrong, and secondarily because it causes ambiguity and leaves the idea to be conveyed indeterminate.

New York, Sept. 3, 1898.

LAMAR LYNDON.

Some Modern Brush Holders.

In an article entitled "Some Modern Brush Holders," which appeared in "The Electrical World" in the issue of July 23, it is inaccurately stated that the C & C Electrical Company use the so-called "reaction brush holders" as licensees under a patent issued by Mr. R. N. Baylis. The principle involved in the reaction brush holder was discovered and patented by Mr. Baylis,

who, however, was at the time chief engineer of the C & C Electric Company, and was materially assisted by that company in making the experiments necessary to the developing and perfecting of the brush holder. The C. & C. Electric Company were the first to use this form of brush holder, and have used it for the last five years, not by license but by proprietary right. May I ask you to publish this letter, with a view to correcting any apprehension on the part of those interested in this subject?

D. W. BARNES,

General Manager C. & C. Electric Company.

New York, Sept. 2, 1898.

Moribund Manhattan.

Your editorial on the "Moribund Manhattan" is one of the most interesting and timely articles which has been published upon this subject. Since coming to New York three years ago I have made a study of the Manhattan Elevated Railroad, and have no hesitation in concurring with Col. Prout, when he says in effect, that the Manhattan Elevated Road is thoroughly well managed, and giving to the people of New York a safe and efficient service. This is certainly a fact, taking the road in its present condition, and considering it as being exclusively a steam railroad. But a steam railroad is not what the people of New York require at the present day, and must certainly be looked upon as somewhat antiquated. After studying the matter closely, I cannot but feel that if the elevated roads were to adopt electric traction, and provide electric elevators at every station, together with comfortable open cars in summer, there would be very few people who would care to patronize the surface cars except for short distances.

CHARLES CAMPBELL, JR.

New York, August 24, 1898.

Electrical Engineering Course at Drexel Institute.
